ABSTRACT

In it of t glut of stud s on t dir ct ion of causality b tw n F or i gn Dir ct Inv s tm nt (FDI) and Infrastructur d v l m nt, m irical vi d nc is not cl ar f or country grou s. This study tr for sought to x lor t corr lat ion b tw n FD I, infrastructur d v l m nt and Growth in Ghana using tim r s data from 1990 and 2015. T c ific obj ct v s includ d t o; xam in t att rn of FDI inflows in Ghana v rt ast two d cad s; xam in t ant c d nt s of FDI inflows into Ghana; xam in t causal r lat ion b tw n FD I and GD Growth; x lor t r lat ion b tw n FD I and infrastructur d v l m nt in Ghana. T data ts wr obtain d fr om t World Bank - African D v l m nt Indicators Databa , t Ministry of Financ and c onomic lanning - Fiscal Data. Ot r ct ions wr com l m nt d w ith data from R and C A ublications. Standard tim - r s unit root t st was conduct d u sing G n ral iz d L a st Squar s D tr nd ing (DF-GLS) to c ck t stationarity of variabl s . Thr main mod l s wr consid r d M od l 1 - Ant c d nt s to FDI; Mod l 2 – Growth Mod l; M od l 3 – Infrastructur Mod l. W ith r ct t o t att rn of FDI inflows into t country, t study found a g n ral incr a in t inflows of for i gn inv s tm nt v rt sam l r iod; how v r it is shown that b tw n 1994 t o 2002 shar falls in t FDI inflows wr r nt. It how v r assum d its st ady r onwards to 2014. For t growth mod l, t study found that av rag growth rat for t 25-y ar r iod was 0.99% far l ss than t annual chang in GD growth of 1.66% for t data an. T long run **Fully Modified Least Square (FMOLS)** s timation show d t hat *nn ss, GD growth rat, xc hang rat fluctuations, olitical risks and r vio us l l of FDI inflows* hav a strong im act on curr nt FD I inflows at 5% significant l v l. In t Two (2) s timation a roac s u d to ca tur t ff ct s of FDI on growth, FDI was shown not to draw any significant im act on growth in both mod l s. T str ngt h of both mod l s is validat d by t adjust d R -squar s of 70.5% in t first mod l and 71.9% in t cond

mod 1. To achieve growth in infrastructure, it is recommended that Government works at nurturing FDI is attractive to sectors of the economy that directly trickles into growth. It is also important that the country's trade policies are geared towards enhancing the country's market for more trade. However, a careful analysis should be done to identify sectors that warrant protection so as not to suffocate nascent industries.

Keywords: Ghana, Foreign Direct Investment, Growth, Infrastructure, Regression.

ACKNOWLEDG M NT

My first a r c iation g s to t Almighty Allah, who through thick and thin has favour d and r ll d m to g tt his far through str ngt h and t wisdom to mbark on this acad m ic nd a vor succ ss fully.

c ondly, I would lik to thank my su r visor, Dr. D - Graft Owusu-Manu, for his su r vision and constant nc ourag m nt dur ing t cour of this r arc h; much a r c iation also g s to Lawr nc Hornuovo for his assistanc in t l ct ion of a r arc h mat r ials and guidanc .

I would also like to extend my sincere appreciation to my family for their support, words of encouragement and constant support throughout my studies. Finally, I would like to express my sincere thanks to all who in various ways have helped to make my research work comfortable officially. Asabir. I also wish to thank all MSc. students 2014/2016 cohort for being a family away from home.

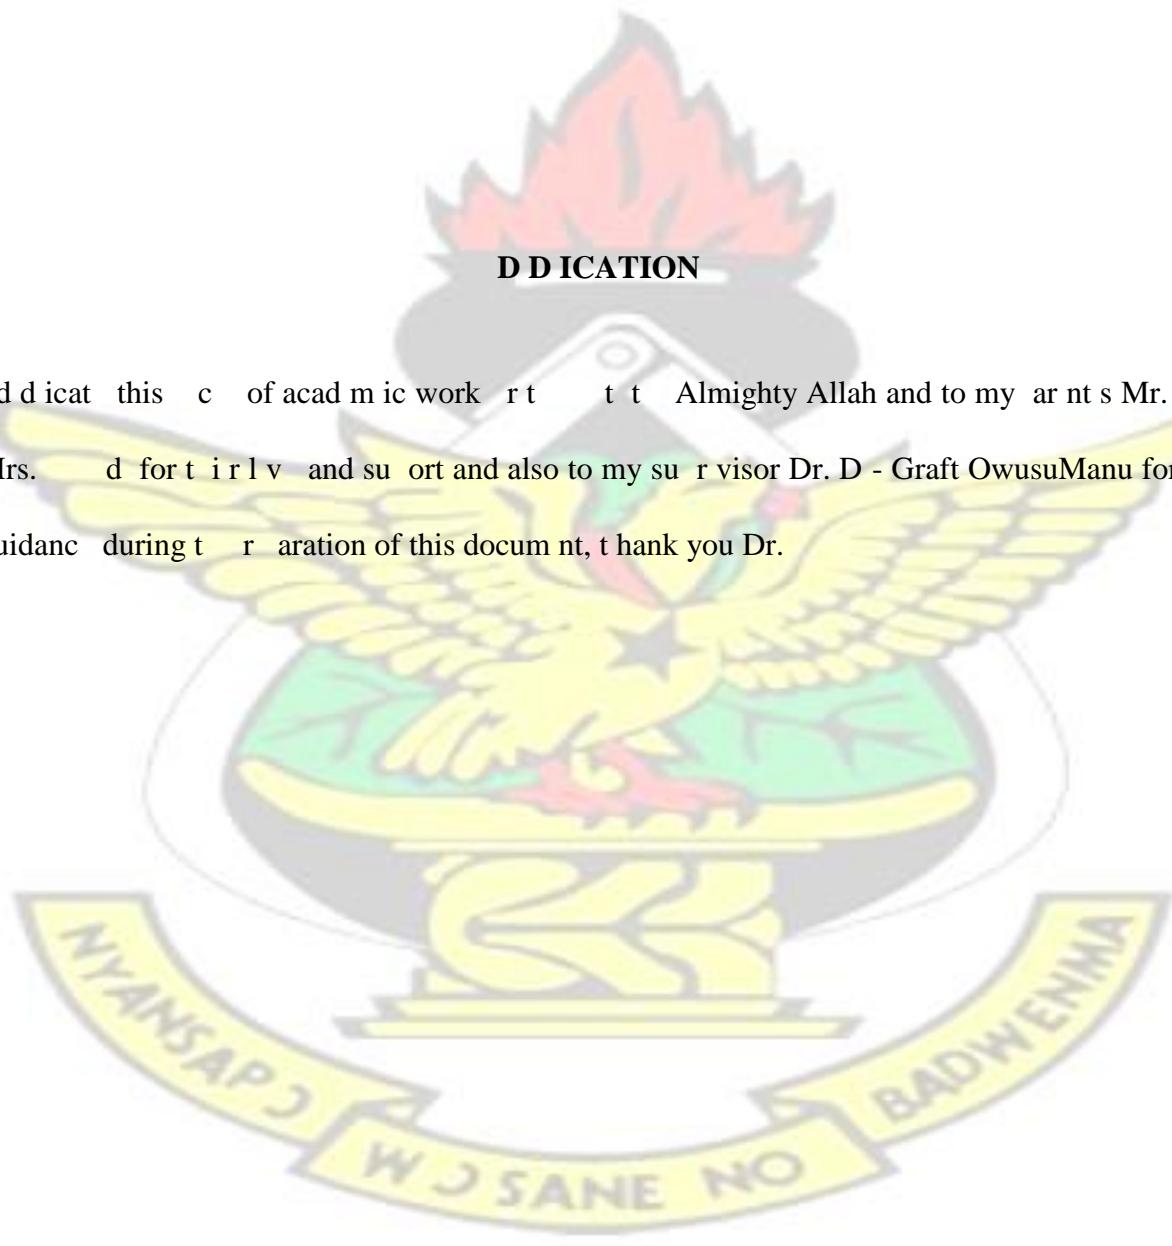

May the Almighty Allah richly bless you all!

KNUST

DEDICATION

I dedicate this chapter of academic work first and foremost to Almighty Allah and to my parents Mr. and Mrs. [redacted] for their love and support and also to my supervisor Dr. D - Graft OwusuManu for his guidance during the preparation of this document, thank you Dr.

INTRODUCTION

1.1 Background of th Study

The wor "s c onomy has x r inc d a tr m ndous incr a s in trad and inv s tm nt b oth in d v l o d and d v l o ing countri s (Kaur t.al, 2013; K arn y, 2007; H rz r t al., 2006) . This tr nd is mor r vasiv in d v l o ing countri s with substantial mark t and abundant labour forc , mak ing th m an attractiv for i gn inv s tm nt d s tination. It is r ort d t hat d v l o ing and transition c onomi s r c i v d m or than half (53%) of th global FDI flows (UNCTAD, 2011). Ind d, Trad and FDI inflows hav b n w id ly r c ognis d a s v ry im ortant factors in th c onomic growth roc ss . ast m irical studi s , both cross country and country s c ific, on

FDI int ract ion on growth and infrastructur d v l o m nt (Balasubramanyam t al, 1996; Bor n szti n t al , 1998; Ko aiboon, 2004; Mansouri, 2005; Karbasi t al, 2005; Li s y, 2000; and ahlavani t al , 2005) hav mostly conclud d t hat FDI inflows romot c onomic growth and infrastructur d v l o m nt. N v rt h1 ss , th r ar cl ar indications that th growth n hancing ff ct s from FDI inflows vary from country to country.

For som countri s FDI can v n n gat iv ly aff ct t h growth roc ss (Balasubramanyam t al., 1996; Bor n szt i n t al., 1998; D M ll o, 1999; Li s y, 2000; and Xu, 2000). Acc ording to Bhagwati"s w ll -known ro osition (call d B hagwati"s hy oth s is) "with du adjustm nt s for diff r nc s among countri s for th i r c onomic siz , olitical attitud s towards FDI and stability, both th magnitud of FDI flows and th i r ff icacy in romoting c onomic growth would b gr at r ov r t h long run. Thus, th growth n hancing ff ct of FDI is not automatic but d nd s on various country s c ific factors such as th trad o nn ss . Similar conclusion is mad by Asi du (2002)

and other studies that an efficient environment that comes with more openness to trade is likely to attract more FDI inflows for faster growth. Empirical studies on the importance of inward FDI in host countries also suggest that the foreign capital inflow augment the supply of funds for investment thus promoting capital formation in the host country (Kandiero and Chitiga, 2003). Again, inward FDI can stimulate local investment by increasing domestic investment through links in the production chain where foreign firms buy locally made inputs or when foreign firms usually source intermediate inputs to local firms (Tsikata et al., 2000). FDIs can also increase the host country's exports causing the developing country to increase its foreign exchange earnings. It is also associated with new job opportunities and enhancement of technology transfer, and boosts overall economic growth in host countries (Mellow, 1999; Herz et al., 2006; Chowdhury and Mavrotas, 2005). A number of firm-level studies, on the other hand, however, do not find support for the view that FDI necessarily promotes infrastructure development.

1.2 **robust Statement**

Despite the literature of studies on the direction of causality between FDI and Infrastructure development (Mellow, 1999; Khodly, 1995; Herz et al., 2006; Chowdhury and Mavrotas, 2005), the empirical evidence is not clear for country groups. Following the criticisms in recent studies (Karmy, 2007; Kaur et al., 2013) of the traditional assumption of a one-way causal link from FDI to Infrastructure development, new studies have also considered the possibility of a bidirectional or non-existent causality between FDI and Infrastructure development. From the numerous existing studies, the causal link between FDI and Infrastructure development is an empirical question that needs to be decided under the set of conditions in the specific host country economy (Kaur et al. 2013;

Hertz et al. 2008; Mansouri, 2005; Chowdhury, and Mavrotas, 2005). Aarntly, m irical d bat s about th causal natur of th rlat ionshi b tw n FD I and infrastructur d v l o m nt ar still subj ct s of conc rn t o macro c onomists b cau s m irical lit ratur s on diff r nt c onomi s also hav conflicting r s ults.

In ass ss ing Gh n "s infrastructur d v l o m nt fr om a contin ntal r s ct iv , th World Bank r ort indicat s that infrastructur contribut d ju st ov r on rc ntag oint to Ghana's annual r ca ita GD growth during th 2000s raising th country" s infrastructur nd owm nt t o that of th r g ion's middl - incom annual growth rat of mor than 2.7 rc ntag oints (World Bank, 2011).

According to th r ort, Ghana has an advanc d infrastructur latform wh n com ar d w ith oth r low-incom countri s in Africa (World Bank, 2011). Th country" s

cov rag l v l s for rural wat r, l ctricity, and GSM signals ar im r ss iv . A larg shar of th road n tw ork is in good or fair condition. Institutional r f orms hav b n ad o t d in th ICT, orts, roads, and wat r su lly s ct ors (Vivian and Nataliya, 2011). Gh n "s most r ss ing chall ng s li in th low r s ct or, wh r outmod d tran smission and distribution ass ts, ra id d mand gr owth, and r iodic hydrological shocks l a v th country r l iant on high-cost oilbas d g n rat ion. xc tionally high loss s in wat r d istribution l a v littl to r ac h nd custom rs, who ar thus x os d t o int rm itt nt su li s . Addr ss ing Ghana's infrastructur chall ng s will r qu ir raising annual x nd itur s to \$2.3 billion (World Bank, 2011). Th country alr ady s nd s about \$1.2 billion r y ar on infrastructur , qu ival nt t o about 7.5 rc nt of GD . A furth r \$1.1 b illion is lost ac h y ar t o in ff ici nc i s , notably und r ricing of ow r. G hana's annual infrastructur funding ga is about \$0.4 billion r y ar, c hi fly r lat d t o ow r and wat r (W orld Bank, 2011). This study th r f or s k s to xam in th corr lat ion b tw n FD I and infrastructur d v l o m nt u sing a s t of conditions in Gh n "s c onomy

cont xt .

1.3 Aims and Obj ct iv

This s ct ion s k s to addr ss th r s arc h aim and obj ct iv s of th study.

1.3.1 R s arc h Aim

This study s t s out to x lor th corr lat ion b tw n FDI and infrastructur d v l o m nt in Ghana using tim s r i s data from 1990 and 2015.

1.3.2 R s arc h Obj ct iv s

In ord r to achi v th abov aim, th study is s c ifically d s ign d to;

1. x lor th tr nd of FDI flow, GD Growth , infrastructur d v l o m nt in Ghana
2. x lor factors and conditions that influ nc FDI inflows into Ghana
3. xam in th causal r lat ionshi b tw n FD I and GD Growth
4. x lor th r lat ionshi b tw n FDI and infrastructur d v l o m nt in Ghana

1.4 R s arc h Qu s tions

Th following qu s tions hav b n d v l o d bas d on th r s arc h ga s id nt ifi d to fulfill th aim and obj ct iv s of th study.

1. What has b n t h att rn of FDI inflows in Ghana, ov r th ast two d cad s ?
2. What conditions aff ct t h d rivation of FDI inflows in Ghana?
3. To what xt nt d os FDI aff ct GD growth in Ghana?

4. Is there any significant relationship between FDI and infrastructure development in Ghana?

1.5 Significance of the study

There are several reasons why the relationship between FDI and infrastructure development must be studied. First, foreign direct investment is an important determinant of the growth process of Ghana. Hence, a literature that would empirically examine the FDI-Infrastructure link is important because increased FDI inflows into the economy should fuel infrastructure growth. The direction of causality between FDI and infrastructure development will be crucial for the formulation of policies that will encourage foreign investors or direct them.

Additional factor that makes this study worth undertaking is that most of the studies on FDI focus on the linkages between FDI, Inflation and growth based on cross country studies. However, the conclusion from such studies may be less relevant at a country level. In addition, aggregated cross-country studies constrain the coefficients of variables. Questions therefore arise about the homogeneity of the sample of the countries in terms of economic reform, structural characteristics and political stability and others. Finally, this study will close the obvious research gap that already exists in the literature. It would also serve as a point of departure for further research in addition to providing information to future researchers who may be interested in studying the inflation-FDI-infrastructure nexus in Ghana.

1.6 Sco of th study

This study xam in d th tr nd of FDI inflows into th country (Ghana) ov r t h ast 2 d cad s ; th und r innig obj ct iv is to id nt ify strat g ic influ nc s that d t rm in th d c ision to locat or inv s t in a articular country or c onomy. Som r v ious studi s (Asi du, 2002; C howdhury, and Mavrotas, 2005; d M ll o, 1999) us d r oad n tw ork, inv s tm nt in tl c ommunication n tw ork, l ctricity cov rag as roxy for infrastructur ; for th ur os of this study, telecom infrastructur and water cov rag would b us d a s roxy for infrastructur . This is b cau s inv s tm nt s in th s two s ct ors hav significant im act on industry and th citiz nry. Th data us d in th m irical analysis would b mainly s c ondary data coll ct d fr om th r iod, 1990 to 2015 consisting of y arly obs r vations for ac h variabl . Th r al GD growth and for i gn dir ct inv s tm nt n t inflows as rc nt of GD (FDI ratio) data would b tak n fr om th World n "s *World D v l o m nt Indicators 2011*.In addition, data will also b coll ct d fr om th Ghana Inv s tm nt romotion C ntr (GIC) as Ghana is th focal oint of this study. Annual tim s r i s data cov r ing th r iod 1990-2015 for which data ar availabl would b us d. Th choic of th s variabl s is as a r s ult of th int rr lationshi and int rd nd nc .

1.7 Ov r vi w of M t hodology

Th study combin d both x lanatory and d s cri tiv r s arc h d s igns; th r s arc h ado ted th functionalist aradigm b cau s of its obj ct ivist and r gulat ory dim n sions. As x lain d by Burr ll and M organ (1979, .26) th functionalist aradigm is robl m -ori nt d in a roach and s k s to rovid r actical solutions to a giv n situation. Th main sourc of data is s c ondary. As FDI figur s would b tak n fr om World Bank r c ords. In analyzing th datas t t h following t s ts would b

m loy d: Un it root t s t for stationarity, Augm nt d D ick y -Full r T s t (ADF), Ordinary L a st Squar (OLS) m t hod, Coint grat ion t s t, V ct or rr or corr ct ion mod 1 (V CM), tc. T h r s arc h r w ill also r ly on statistical com uting softwar (stata) to im l m nt th tim s r i s m t hods and all statistical t s ts would b carri d out at 0.05 l v 1 of significanc .

1.8 Organization of th Study

Th study is organiz d into fiv cha t r s. Th first cha t r is th introduction which cov r s th background to th study, robl m stat m nt, research aim and objectives, hy oth s is, justification of th study and organization of th study. Cha t r tw o r s nt s summary of th x isting th o r tical and m irical lit ratur on FDI and infrastructur d v l o m nt . Cha t r t hr d al s with th m t hodology for th study; Cha t r f our focus s on mod l s s timation and data analysis. Cha t r fiv com ris s of summary, conclusions and olicy r c omm ndat ions. Figur

CHAPTER TWO

LIT RATUR R V I W

2.1 Introduction

This chapter reviews relevant theoretical and empirical literature on the linkages between foreign direct investment and infrastructure development in Ghana. The first section explores global FDI flows and driving factors; the second section examines empirical literature of FDI flows whilst the last section draws conclusions from both the theoretical and empirical literature.

2.2 Global picture of Foreign Direct Investment

Growth in FDI accelerated in the 1990s, rising to \$331 billion in 1995 and \$1.3 trillion in 2000 (UNCTAD, 2002). As a result, developing countries including India saw increases in the average ratio of FDI to total investment during the 1990s. A principal factor of the growth in FDI has been its rise in the services sector, which is now the dominant sector in global FDI. For developing countries, FDI in services increased at an annual rate of 28% over the period 1988 to 1999, and by 1999, accounted for 37% of total foreign investment inflows. A significant part of the increase in FDI in the services sector has been the growth in private capital flows for infrastructure investments to the general trend towards privatization of infrastructure in developing countries (WIR, 2012). In contrast, there was a sharp decline in donor support for infrastructure projects during the 1990s, with aggregate flows of official development assistance for the infrastructure industries falling by half during the course of the decade (Willoughby, 2002). Private sector participation in infrastructure projects in developing countries has risen dramatically since 1990 and the annual investment commitment reached a peak of \$128 billion in 1997. According to the World Bank's participation in Infrastructure (I) database, 26 countries awarded 72 infrastructure projects with

rivate participation in 1984-89, attracting almost \$19 billion in investment commitments. In the 1990s, 132 low- and middle-income countries used private participation in infrastructure – 57 of them in three or all four of these sectors covered in the database (transport, energy, telecommunications, and water and sewerage). In 1990-2001, developing countries transferred about the private sector the responsibility for almost 2,500 infrastructure projects, attracting investments worth more than \$750 billion (WIR, 2002).

Studies show that Global FDI inflows have not been consistent (Chowdhury, and Mavrotas, 2005; Asiedu, 2002; Sabra, and Flacchini, 2005). In 2012 for instance, foreign direct investment (FDI) inflows is reported to have declined in all three major economic groups – developing, developing and transition economies, although at different rates (WIR, 2012). In developing countries, FDI flows fell by 32 percent to \$561 billion, a little less than half a year ago. These records also show that majority of European Union (EU) countries and the United States experienced significant drops in their FDI inflows (WIR, 2012). Interestingly, FDI inflows to developing economies remained relatively stable, declining by only 4 percent, accounting for 52 percent of global inflows in 2012. Flows to areas such as developing Asia and Latin America and the Caribbean lost some momentum, although they remained at historically high levels. All sub-regions in developing Asia – East and South Asia, South Asia and West Asia – saw their flows decline in 2012, compared with the previous year (World Bank, 2012). FDI inflows to the structurally weak, vulnerable and small economies further in 2012 from a small base of \$56 billion in 2011 to \$60 billion, owing to the strong growth of FDI to least developed countries (LDCs) and small island developing states (SIDS). Their share in the world total also rose, to 4.4 percent from 3.4 percent in 2011 (World Bank, 2012). Outward FDI from developing economies declined by \$274 billion in 2012, accounting for almost all of the fall in global outward FDI; in

contrast to the share decline of FDI flows from developing countries, FDI flows from developing countries increased by 1 percent in 2012, amounting to \$426 billion. As a result, their share in global outflows reached a record 31 percent. FDI outflows from Africa almost tripled; flows from Asia and Latin America and the Caribbean remained almost at the 2011 level (World Bank, 2012).

Africa is one of the few regions to enjoy year-on-year growth in FDI inflows since 2010. Investment in exploration and exploitation of natural resources, and high flows from China both contributed to the current level of inward flows (WIR, 2012). Moreover, by the continent's good economic performance – GDP growth was estimated at 5 percent in 2012 – underpinned the rise in investment, including manufacturing and services. In contrast, FDI flows to West Africa declined by 5 percent, to \$16.8 billion, to a large extent because of declining flows to Nigeria. With demand driven by political instability and the weak global economy, that country saw FDI inflows fall from \$8.9 billion in 2011 to \$7.0 billion in 2012 (World Bank, 2012). Meanwhile, Liberia and Mauritania both experienced a surge in inward FDI flows. In Mauritania, FDI inflows doubled to \$1.2 billion, which can be attributed in part to the expansion in mining operations (copper and gold) by Canadian-based First Quantum Minerals and Kinross. Central Africa attracted \$10 billion of FDI in 2012, a surge of 23 percent on the previous year. Slowing FDI inflows to the Congo were offset by an increase to the Democratic Republic of the Congo, where inward FDI flows jumped from \$1.7 billion to \$3.3 billion. Some of the flows went towards the expansion of the copper-cobalt Tchumtchum Fungurume mine. Recent natural resource discoveries also contributed to the increase in FDI inflows to East Africa, from \$4.6 billion in 2011 to \$6.3 billion in 2012. This includes investment recently discovered gas reserves in the

United Republic of Tanzania and oil fields in Uganda (WIR, 2012). Outward FDI flows from Africa nearly tripled in 2012, from \$5 billion in the previous year to an estimated \$14 billion. South

African companies were active in acquiring operations in mining, which was from the country to \$4.4 billion in 2012. The growth in investment from South Africa, coupled with year-on-year increases in FDI outflows from Angola, resulted in a significant expansion of overseas investment activities from the Southern African region. Central Africa, North Africa and West Africa also recorded significant rises in their outflows in 2012, boosted primarily by increases from the Democratic Republic of the Congo, Libya and Nigeria (WIR, 2012).

2.2.1 Foreign Direct Investment inflow in Ghana since 1990 – 2015

One of the economic problems of developing countries is that, they do not have enough national savings to finance their investments. They are in constant need of foreign capital in forms of both direct and indirect investments. Initially, they took loans from international commercial banks. But in the 1980s, the drying-up of commercial bank lending, because of debt crises, forced many countries to reform their investment policies so as to attract more stable forms of foreign capital, and FDI as a alternative of the easiest way to get foreign capital without undertaking any risks linked to the debt (WIR, 2012). Thus, it became an attractive alternative to bank loans as a source of capital inflows. Agiomirgianakis *et al.* (2003) mention that FDI is mostly defined as capital flows resulting from the behaviour of multinational companies (MNCs). Thus, the factors to affect the behaviour of MNCs may also affect the magnitude and the direction of FDI. MNCs expand their activities to a foreign country for a number of reasons including, among others, the exploitation of economies of scale / scope, the use of specific advantages, often owing to a life-cycle attrition of their products or just because their competitors are engaged in similar activities.

On the other hand, governments are also engaged in a policy competition by changing key factors of their economic policies, such as domestic labour market conditions, corporate taxes, tariff barriers

r s, subsid s , rivatization and r gulat ory r g im olic s so as to im rov FDI activity in th i r countri s .

For i gn dir ct inv s tm nt (FDI) inflows to low-incom countri s has not only r c i v d muc h ublicity in th ast two d cad s du to its c onomic im ortanc , but its ov rall fl ow to th s countri s has also significantly incr a s d in both r lat iv and absolut t rm s. How v r, only a f w sub-Saharan African countri s hav b n succ ss ful in attracting significant FDI inflows. Globally, Afri "s shar of FDI to world" FDI inflows ros from 1 rc nt in 2000 to 2 rc nt in 2001(UNCTAD, 2002), a gr at r shar going to r s ourc rich countri s such as Alg r ia, Angola, gy t, South Africa, and Nig r ia (Kandi r o and Chitiga, 2003). Th historical tr nd of FDI inflows in Ghana can b shown in thr main has s sinc 1983 (Tsikata *et al.*, 2000). Th r iod 1983-88 witn ss d sluggish inflows, av rag ing about \$4 million r annum, and t h high s t and low s t inflows during th r iod b i ng \$6 million in 1985 and \$2 million in 1984 r s ct iv ly. Th r iod 1989-1992 r c ord d m od rat inflows av rag ing about \$18 million r annum th high s t and low s t b i ng \$22 million in 1992 and \$14.8 million in 1990 r s ct iv ly. Th 1993-1996 was a r iod of significant, but oscillatory inflows, which ak d in 1994 at \$233 million, but f ll by m or than 50% th following y ar t o \$107 million. Th lat s t valu for For i gn dir ct inv s tm nt, n t (B o , curr nt U S\$) in Ghana was (\$3,226,300,000.00) as of 2013. Ov r t h ast 8 y ar s, th valu for this indicator has fluctuat d b tw n (\$144,970,000.00) in 2005 and (\$3,293,430,000.00) in 2012.

Tabl 2.1: FDI Inflow in Ghana

| Y ar | Valu | Y ar | Valu |
|------|-----------------|------|------------------|
| 1975 | \$70,869,950.00 | 1994 | \$233,000,000.00 |

Sourc : World Bank Data bas (2013)

An equally important feature of the FDI inflows according to Tsikata et al (2000) is the three-way nexus of economic growth, investment and political stability, which has emerged since the country's independence in 1972. In 1972, a growth rate of 2.3% was recorded, accompanied by a more than 60% drop in FDI (from \$30.6 million in 1971 to \$11.5 million in 1972). Similar trends were recorded after the years 1979 and 1981 coinciding with growth falling to as low as -3.2%; there was also an outflow of \$2.8 million of FDI. The state of the economy worsened further with annual growth rates of -3.5% in 1981 to -6.9% in 1982; however, the inflow of FDI remained constant at \$16.3 million. The relationship between parliamentary democracy was restored in 1992. The rate of growth of 5.3% in 1991 fell to 3.9% in 1992; this has been variously attributed to oil deficit financing and taking into account the democratic process. The FDI flow however, increased from \$20 million in 1991 to \$22.5 million in 1992 excluding investment in the mining sector.

2.3 Determinants of Foreign Direct Investment

There are many theories which attempt to explain the determinants of FDI. These theories are significant steps towards the development of a systematic framework for the management of FDI.

How various characteristics of each to survive as a self-contained general theory which could explain all types of FDI (i.e., outward as well as inward FDI at the firm, industry, and country level) has been questioned in the works of various scholars. Agarwal (1980), Barry (1985), Itaki (1991) can be given as examples. Dunning is one of the most referenced by authors working on FDI. Dunning (1993) describes three main types of FDI based on the motives behind investment from the perspective of the investing firm. The first type of FDI is called *marketing FDI*, whose aim is to serve local and regional markets. It is also called horizontal FDI, as it involves relocation of production facilities in the host country. Tariff-jumping or short-substituting FDI is a variant of this type of FDI. This is because the reason for horizontal FDI is to benefit from a local market by local production, market size and market growth of the host economy playing important roles. Obstacles to accessing local markets, such as tariffs and transportation costs, also encourage this type of FDI. The second type of FDI is called *resource-seeking*: when firms invest abroad to obtain resources not available in the home country, such as natural resources, raw materials, or low-cost labour (Dunning, 1993). Particularly in the manufacturing sector, when multinationals directly invest in order to export, factor-cost considerations become important. In contrast to horizontal FDI, vertical or short-oriented FDI involves relocating parts of the production chain to the host country. Availability of low-cost labour is a major driving force for short-oriented FDI. Naturally, FDI in the resource sector, such as oil and natural gas, is attracted to countries with plentiful natural endowments (World Bank, 2012). The third type of FDI, called *efficiency-seeking*, takes place when the firm can gain from the common government of geographically dispersed activities in the sense of economies of scale and scope (WIR, 2012).

In 1998, the World Investment Report, UNCTAD (1998) has analyzed the determinants of FDI and host country determinants have been classified into three groups. These are political factors,

business facilitation and economic factors. The absence of a generally accepted theoretical framework has led researchers to rely on empirical evidence for explaining the emergence of FDI (ADB, 2004).

2.3.1 Market Size

Artigas and Nicolini (2005) state that market size as measured by GDP or GDI *per capita* seems to be the most robust FDI determinant in economic studies. This is the main determinant for horizontal FDI. It is irrelevant for vertical FDI. Jordaan (2004) maintains that FDI will move to countries with larger and expanding markets and greater purchasing power, where firms can potentially receive a higher return on their capital and by implication receive a high profit from their investments. Charkrabarti (2001) states that the market size hypothesis supports an idea that a large market is required for efficient utilization of resources and exploitation of economies of scale: as the market size grows to some critical value, FDI will start to increase sharply with its further expansion. This hypothesis is based on it being a variable representing the size of the host country market has come out as an explanatory variable in nearly all empirical studies on determinants of FDI (Bouoiyour, 2003). In ODI (1997), it is stated that economic studies comparing a cross section of countries point to a well-established correlation between FDI and the size of the market, which is a proxy for the size of GDP, as well as some of its characteristics, such as average income levels and growth rates. Some studies found GDP growth rate to be a significant explanatory variable, whereas GDP was not, probably indicating that whether the current size of national income is very small, increases may have less relevance to FDI decisions than growth performance, as an indicator of market potential. Theoretical results on market size are far from being unanimous. Edwards (1990) and Jansen et al. (2000) use the inverse of income per capita as a proxy for the

turn on capital and conclude that real GDP (r_{capita}) is inversely related to FDI/GDP, but Schnieders and Fréry (1985), Tsiros (1994) and Asiadu (2002) find a positive relationship between the two variables. They argue that a high real GDP (r_{capita}) is likely to be associated with FDI in the host country. Ärlund (2008) finds that the variable GDP is positive and statistically significant at less than 1% level. She argues that the enlargement of market size tends to stimulate the attraction of FDI to the economy. Ang (2008) finds that real GDP has a significant positive impact on FDI inflows. He also finds that growth rate of GDP exports a small positive impact on inward FDI.

2.3.2 Ownership

Chakrabarti (2001) states that there is mixed evidence concerning the significance of ownership, which is measured mostly by the ratio of exports to GDP, in determining FDI, as well. They maintain the hypothesis that most investments projects are directed towards the tradable sector, a country's degree of openness to international trade should be a relevant factor in the decision. Jordaan (2004) claims that the impact of ownership on FDI depends on the type of investment. When investments are market-seeking, trade restrictions (and therefore less openness) can have a positive impact on FDI. The reason stems from the "tariff-jumping" hypothesis, which argues that foreign firms that seek to serve local markets may decide to establish subsidiaries in the host country if it is difficult to import their products to the country. In contrast, multinational firms engaged in export-oriented investments may prefer to invest in a more open economy since increased imports that accompany any trade restriction generally imply high transaction costs associated with exporting. While Kravis and Mody (1992) observe a strong positive support for the hypothesis in the manufacturing sector, but a weak negative link in the electronic sector. Kravis and Li Sy (1982), Culm (1988), Edwards (1990) find a strong positive effect of ownership on FDI and Schmitz and Bierri (1972) obtain a weak positive link. Ärlund (2008) finds that *trademark* ownership is positive but

statistically significant from zero. In ODI (1997), it is stated that while access to specific markets – judged by their size and growth – is important, domestic market factors are relatively much less relevant in export-oriented foreign firms. A range of surveys suggests a widespread recognition that “open” economies encourage more foreign investment.

2.3.3 Labour Costs and Productivity

Charkrabarti (2001) claims that wages as an indicator of labour cost has been the most contentious of all the potential determinants of FDI. Historically, the importance of cheap labour in attracting multinationals is argued upon by theorists of the demand theory which holds that as well as those of the modernization theorists, though with very different implications. There is, however, no unanimity even among the comparatively small number of studies that have explored the role of wages in affecting FDI: results range from high-host country wages discouraging inbound FDI to having no significant effect or even a positive association. There is no unanimity in the studies regarding the role of wages in attracting FDI. Goldsbrough (1979), Saunders (1982), Flamm (1984), Schnieder and Fry (1985), Culm (1988), and Shamsuddin (1994) demonstrate that higher wages discourage FDI. Tsai (1994) obtains strong support for the cheap-labour hypothesis over the period 1983 to 1986, but weak support from 1975 to 1978. In ODI (1997), it is stated that geographical research has also found relatively low labour costs to be statistically significant, particularly for foreign investment in labour-intensive industries and for export-oriented subsidiaries. However, while the cost of labour is relatively insignificant (when wages rates vary little from country to country), the skills of the labour force are expected to have an impact on decisions about FDI location.

2.3.4 Political Risk

The ranking of political risk among FDI claimants remains rather unclear. According to ODI (1997), where the host country owns rich natural resources, no further incentive may be required, as it is seen in politically unstable countries, such as Nigeria and Angola, where high returns in the extractive industries seem to contribute to political instability. In general, as long as the foreign company is confident of being able to operate profitably without exposing itself to its capital and personnel, it will continue to invest. For example, large mining companies overcome some of the political risks by investing in their own infrastructure maintenance and their own security forces (Jarsen et al., 2000). Moreover, these companies are limited in their by small local markets not by exchange-rate risks since they tend to sell almost exclusively on the international market at hard currency rates. Specific proxy variables (e.g. number of strikes and riots, work days lost, etc.) have proved significant in some studies; but these quantitative estimates can capture only some aspects of the qualitative nature of political risk.

Empirical relationships between political instability and FDI flows is unclear. For example, Jarsen et al. (2000) and Hausmann and Fernández-Arias (2000) find no relationship between FDI flows and political risk while Schnider and Fry (1985) find an inverse relationship between the two variables. Using data on U.S. FDI for two time periods, Lorch and Guisinger (1995) found that political risk had a negative impact on FDI in 1982 but no effect in 1977. Edwards (1990) uses two indicators, namely political instability and political violence, to measure political risk. Political instability (which measures the probability of a change of government) was found to be significant, while political violence (i.e. the frequency of political assassinations, violent riots and politically motivated strikes) was found to be insignificant.

2.3.5 Infrastructur

Infrastructur cov r s many dim n sions ranging from roads, ports, railways and t l c ommunication syst m s to institutional d v l o m nt (.g. accounting, legal s r vic s , tc.). According to ODI (1997), poor infrastructur can b e s en, how v er, as both an obstacl and an o portunity for for i gn inv s tm nt. For th majority of low-incom countri s , it is oft n c it d as on of th major constraints. But for i gn inv s tors also point to th pot ntial for attracting significant FDI if host gov rnm nt s rm it mor substantial for i gn artici ation in th infrastructur s ct or. Jordaan (2004) claims that good quality and w ll -d v l o d infrastructur incr ass th productivity ot ntial of inv s tm nt s in a country and th r f or stimulates FDI flows towards th country. According to Asi du (2002) and Anc haraz (2003), th numb r of t l hon s /r 1,000 inhabitants is a standard m a sur m nt in th lit ratur for infrastructur d v l o m nt. How v er, acc ording to Asi du (2002), t his m a sur falls short, b cau s it only ca tur s th availability and not th r l iability of th infrastructur . Furt h rm or , it only includ s fix d -lin infrastructur and not c llular (m obil) t l hon s .

2.3.6 Growth

Th rol of growth in attracting FDI has also b e n t h subj ct of controv r sy; Charkrabarti (2001) stat s that th growth hy oth s is d v l o d by L im (1983) maintain d t hat a ra idly growing c onomy rovid s r lat iv ly b tt r o ortuniti s for making rofits than th on s growing slowly or not growing at all. Lunn (1980), Schn i d r and Fr y (1985) and Cul m (1988) find a significantly ositiv ff ct of growth on FDI, whil Tsai (1994) obtains a strong su ort for th hy oth s is ov r t h r iod 1983 to 1986, but only a w ak link from 1975 to 1978. On th oth r hand, Nigh (1985) r orts a w ak ositiv corr lat ion for th lss d v l o d c onomi s and a w ak

n gat iv corr lat ion for th d v lo d c ountri s . Ancharaz (2003) finds a ositiv ff ct with lagg d gr owth for th full sam l and for th non-Sub-Saharan African countri s , but an insignificant ff ct f or th Sub-Saharan Africa sam l . Ga stanaga *tal.* (1998) and Schn i d r and Fr y (1985) f ound ositiv significant ff ct s of growth on FDI.

2.3.7 Tax

The lit ratur r ma ins fairly ind c isiv r gard ing wh t h r FD I may b s n sitiv to tax inc ntiv s .

Som studi s hav shown that host country cor orat tax s hav a significant n gat iv ff ct on FDI flows. Oth r s hav r ort d t hat tax s do not hav a significant ff ct on FDI. Hartman (1994), Grub rt and Mutt i (1991), Hin s and Ric (1994), Lor and Guising r (1995), Ca ssou (1997) and K m sl y (1998) f ind that host country cor orat incom tax s hav a significant n gat iv ff ct on attracting FDI flows. How v r, R oot and Ahm d (1979), L im (1983), Wh l r and Mody (1992), Jackson and Markowski (1995), Yulin and R d (1995) and orcano and ric (1996) conclud that tax s do not hav a significant ff ct on FDI. Sw n son (1994) r orts a ositiv corr lat ion. Th dir ct ion of th ff ct s of abov m nt ion d d t rm inants on FDI may b diff r nt. A variabl may aff ct FD I both ositiv ly and n gat iv ly. For xam l , fact ors, such as labour costs, trad barri r s, trad balanc , xc hang rat and tax hav b n f ound to hav both n gat iv and ositiv ff ct s on FDI. In th m irical studi s various combination of th s d t rm inants as x lanatory variabl s hav b n u s d. M oosa (2005) stat s that du to th abs nc of a cons n sus on a th o r t ical fram w ork to guid m irical work on FDI, th r is no wid ly acc t d s t of x lanatory variabl s that can b r gard d as th “tru ” t rm inants of FDI.

2.4 International Investment Theories

The early works of FDI theory can be traced in the work by MacDougall (1958) who established his model based on the assumptions of perfect competition and market. His theory was further elaborated by Krugman (1964). Assuming a two-country model and prices of capital being equal to its marginal productivity, MacDougall and Krugman both stated that when there was free movement of capital from an investing country to a host country, the marginal productivity of capital tends to be equalized between the two countries. They found that free movement, thus, out of the investing country follows without any decrease in the national income of the country. This is because in the long term the investing country gets high returns from its investment abroad.

2.4.1 Industrial organization approach

Hymans was one of the pioneers who established a systematic approach towards the study of FDI. In his 1960 doctoral dissertation, Hymans (1976) developed the FDI theory approach of industrial organization. His theory, which was one of the first works to explain international production in an imperfect market framework, was supported by Leontief (1961), Kindleberger (1969), Knickerbocker (1973), Cavus (1974), Dunning (1974), Vaitsos (1974) and Cohen (1975) among others. The significance of Hymans' theory is that firms operating abroad have to compete with domestic firms that are in an advantageous position in terms of culture, language, legal system and consumer preference. Furthermore, foreign firms are also exposed to foreign exchange risk. These disadvantages must be offset by some form of market power in order to make international investment profitable.

2.4.2 FDI based on monopolistic power

Kindleberger (1969), by extending the work of Hymer, put forward his theory of FDI on the basis of monopolistic power. Kindleberger argued that advantages enjoyed by MNCs could be used only in the case of market interaction. The advantages described by him might be in the form of superior technology, managerial expertise, contacts. These advantages generally encourage a firm to invest in a foreign country in order to fully exploit them instead of sharing them with potential competitors in the foreign market. The greatest chance of earning monopoly profits, the high reward will be the encouragement of foreign firms to invest directly. Although, Kindleberger described various forms of advantages generally enjoyed by a firm over the host country firm, he failed to describe which advantage a firm should focus on. Further, a firm can exploit its monopolistic advantages abroad only if the host country's policy allows it to do so. Generally, in the name of national interest, the host government would be unwilling to permit foreign firms into the country.

2.4.3 Internationalization theory of FDI

Buckley and Casson (1976) provided another explanation of FDI by putting emphasis on internationalization and technology. They shifted the focus of the international investment theory from country-specific towards industry-level and firm-level determinants of FDI (Henisz, 2003).

Buckley and Casson analyzed MNCs within a broad-based framework developed by Coase (1937). This theory came to be known as internationalization theory as they stressed that this fact with regard to the creation of MNCs. They articulated this theory based on three postulates:

- (a) Firms maximize profits in a market that is imperfect;

(b) When marks in intermediate products are imported, there is an incentive to bypass them by creating internal marks.

(c) Internationalization of marks across the world leads to MNCs.

2.4.4 Oligopolistic theory x plain FDI

Knight (1973) also formulated his theory based on market import restrictions. It has been asserted in the economic literature that there are two important motives for choosing a particular country as a location for setting up a new facility: (a) firms seek increased access to the host country's market; and (b) firms want to utilize relatively abundant factors available in that country. Knight also cited a third motivation for choosing a location – firms might invest in a country to match a rival's move (Haddad and others, 2002). In other words, firms often exhibit imitative behaviour, i.e., they follow the internationalization of competitors so that they will not lose their strategic advantage. In particular, Knight argued that in oligopolistic market conditions, firms in an industry tend to follow each other's location decision. The idea is that firms, uncertain of production costs in the country to which they are currently exporting, run the risk of being undercut by a rival switching from exporting to setting up a manufacturing subsidiary in the host country. By imitating the rival's FDI, the firm can avoid being undercut (Altomonte and Cannings, 2003).

2.4.5 eclectic paradigm to FDI

In the 1970s one of the most robust and comprehensive theories of FDI was developed by Dunning (Rade, 2007). In his path-breaking work, Dunning (1977 and 1979) amalgamated the major import market-based theories discussed above – the oligopolistic and internationalization theories – and added a third dimension in the form of location theory to explain why a firm chooses a foreign

subsidiary. Location theory addresses the important questions of who produces what goods or services in which locations, and why? Location theory has also been frequently applied by researchers in attempting to understand the factors that influence the locations of MNC units. Among others, they number raters such as host country policies, economic fundamentalists, firm strategy and agglomeration economies.

Furthermore, endogenous growth theory claims that economic growth is mainly generated by factors like economies of scale, increasing returns or induced technological changes which are within the production process. Romer (1990) and Grossman and Helpman (1991) develop growth models within the endogenous growth theory to explain the relationship between FDI and growth. These models assume that technological progress is the principal driving force of economic growth. The theories focus on the creation of technological knowledge and its transfer, and view innovation as major engines for growth. Therefore, these models lack emphasis on human capital accumulation and externalities on growth. In this regard, growth rate of developing economies is seen to be contingent on the extent to which these countries can accept and utilize innovative technologies available in highly developed economies. They argue that FDI is the main channel for the process of advanced technologies by developing countries (Sabra, and

Flach, 2005). Developing countries generally are not able to innovate and generate new technologies. Therefore, they have to adopt technology that is produced from advanced countries through the channel of FDI.

The new growth theorists indicate bidirectional causality between FDI and growth (Blomstrom et al., 1996; Bornstein et al., 1998). This is because FDI is exerted to hand in improving economic growth by encouraging the incorporation of new inputs and for introducing technologies in the production function of the beneficiary country. In addition, FDI enhances growth by adding to the

host country, existing knowledge bases through human resource training and development. Also FDI increases competition in the host country by overcoming entry barriers and producing the market power of existing firms (Dunning 1993; Blomstrom et al., 1996; Bornstein et al., 1998 and D' Mello, 1999). Nevertheless, Dowling and Himmelfarb (1982) and Lewis and Rana (1986) contend that rapid economic growth also induces the FDI inflows. This is explained by the reason that high sustainable growth usually creates high levels of capital requirements in the recipient economy and as a result, the host country needs more FDI by creating the necessary macroeconomic climate to attract foreign investors. Thus, rapid growth in the host nation also builds the self-assurance of foreign investors investing in the host country. Thus, both FDI and economic growth are positively and largely bidirectional causality.

2.5 Empirical Review on Foreign Direct Investment and Growth

Balasubramanyam et al. (1996) used cross-country data averaging over the period 1970-1985 for a sample of 46 developing countries and found that trade openness is crucial for acquiring the potential growth impact of FDI. Moreover, this study indicates that FDI has strong effects on growth than domestic investment, which may be viewed as a confirmation of the hypothesis that FDI acts as a vehicle for international technology transfer. Bornstein et al. (1998) tested the correlation between FDI and GDP in a cross-country regression framework with 69 developing countries over two separate time periods 1970-1979 and 1980-1989. They discovered that the effect of FDI on growth depends on the level of human capital in the host country and that FDI has positive growth effects only if the level of education is higher than a given threshold. Thus, the findings of Bornstein et al. support the results of Bornstein et al. that FDI positively affects growth. However, both studies failed to check for directional causality between the two variables. Zhang (2000) empirically examined cointegration and causality between FDI and growth for 11 developing

ing countries in East Asia and Latin America over the period 1970-1995. The findings indicate a positive relationship between FDI and growth and a Granger causality from FDI to GD for five countries. In addition, Bond et al. (2001) also studied the relationship between FDI and growth in four developing countries using annual time series data over the period 1970-1998. The results show a positive and significant relationship between FDI and growth. Thus both studies agree that FDI relates positively with growth and that FDI stimulates growth in developing countries. Cho (2003) used annual data to investigate how FDI and economic growth relate in eighty countries over the period 1971-1995. The results confirm the validity of Granger causality relating between FDI and economic growth in third direction. Basu et al. (2003) agree with Cho when they also find both co-integration and causality tests to study the causality between FDI and growth using a panel of 23 developing countries over the period 1978-1996. They found a positive relationship between FDI and GD. Their results indicate bidirectional causality between the two variables for one economy. Chowdhury and Mavrotas (2003) empirically look at the linkages between FDI and GD growth using annual time series data covering the period 1969 to 2000 for thirty developing countries. They employ Johansen and Granger causality tests and establish a positive connection between FDI and GD growth and causality that runs from both directions. Thus, the empirical findings of Chowdhury and Mavrotas support the results obtained by Basu et al. (2003).

The results by Ramírez (2000) indicate that for the period 1960-1995, FDI Granger-causes growth in Mexico. The study also establishes a positive relationship between FDI and growth in both the short and the long run relationships. In addition, Athukorala (2003) examine the relationship between FDI and growth using time series data from the Sri-Lankan economy. The econometric results show a positive and significant relationship between FDI and economic growth. The study also

s tablish d a un idir ct ional causality from growth to FDI. As s n fr om th two studi s , th diff r nc in r s ults could b du to th diff r nc in s timation t c hniqu s . Whil s Ramíz us d th Johans n coint grat ion a roach, Athukorala m loyd th BoundsT s t to coint grat ion. Th diff r nc in sam l siz s could also contribut to th variation in th findings of th two studi s . Dritsaki, t al. (2004) inv s tigat d t h r lat ionshi b tw n trad , FDI and c onomic growth for Gr c ov r t h r iod 1960-2002. Th coint grat ion analysis r v al d t hat th r is a long run qu ilibrium r lat ionshi . Abdus Samad (2009) cont nd d w ith H rz r t al w h n h analyz d t h r lat ionshi b tw n f or i gn dir ct inv s tm nt and c onomic growth for 19 d v 1 o ing countri s of South- a st Asia and Latin Am r ica. Th study m loy d t h co-int grat ion t c hniqu , Grang r cau sality t s t and rr or Corr ct ion Mod l to analyz th variabl s . Th r s ults confirm d a un idir ct ional causality that runs from c onomic growth to for i gn dir ct inv s tm nt for fiv countri s in Latin Am r ica and on country in a st and South a st Asia. In addition, th author r ort d a tw o-way causal r lat ionshi b tw n f or i gn dir ct inv s tm nt and c onomic growth for s v n c ountri s (two from Latin Am r ica and fiv from a st and South a st Asia). Lastly, a unidir ct ional short run causal link that runs from c onomic growth to for i gn dir ct inv s tm nt wa s found in four countri s (on from Lain Am r ica and thr from a st and South a st Asia).

Anowar and Mohammad (2011) look d at how for i gn dir ct inv s tm nt and c onomic growth int ract in Banglad s h, akistan and India ov r t h r iod of 1972 to 2008. Th y u s d th J ohans n a roach to co int grat ion and th Grang r cau sality t s t. Th findings indicat d t hat th r is no co int grat on r lat ionshi b tw n FD I and c onomic growth in Banglad s h and India but th r is

a ositiv co int grat ion r lat ionshi b tw n FD I and growth in akistan. On th oth r hand th causality t s t show d t hat th r is no dir ct ional causality b tw n GD and FDI for Banglad s h. Quis r t al. (2011) inv s tigat d t h im act of for i gn dir ct inv s tm nt on Growth of South Asian Association for R g ional Coo rat ion countri s . This r lat ionshi was t s t d by a lying multi l r gr ss ion mod l s. Th chang in GD is tak n a s d nd nt viabl whil FDI and inflation ar consid r d a s ind nd nt variabl s . Th data us d f or this is ranging from y ar 2001 t o 2010. Th r s ult show d t hat th ov rall m od l is significant. Th r is a ositiv and significant r lat ionshi b tw n GD and FDI. Th findings of Quis r t al c onflict with that of Anowar and Mohammad b cau s of diff r nc in m t hodology, data and sam l siz . Furt h rm or , L o ss t al. (2010) xam in d t h linkag and dir ct ional causality b tw n FDI and growth of t n Sub-Saharan African countri s using annual tim s r i s data from 1970 to 2007. Th y m loy d t h s aran t al. (2001) a roach to co int grat ion and th Toda and Yamamoto (1995) causality t s t and r al iz d a ositiv and significant long run r lat ionshi b tw n FD I and GD growth in Angola, Lib r ia, K nya and South Africa. How v r, t h y found a unidir ct ional causality running from FDI to GD growth. Both Lo ss t al and Ogiaghah t al. hav th sam o inion on th r lat ionshi b tw n FD I and growth. How v r, t h diff r nc in dir ct ional causality could b du to th diff r nc in m t hodology. Annual tim s r i s and an l data may not yi ld t h sam r s ults. Lastly th two c onom tr ic t c hniqus - Grang r cau sality and Toda and Yamomanto could also yi ld t h diff r nt r s ults.

Sum i -Tang t al. (2008) xam in th causal link b tw n f or i gn dir ct inv s tm nt, d om s tic inv s tm nt and c onomic growth in China ov r t h r iod 1988-2003. Th study confirm d a unidir ct ional causality that runs from for i gn dir ct inv s tm nt t o c onomic growth. Th authors conclud d t hat for i gn dir ct inv s tm nt has h l d in ca ital formation, in addition to acc l rat

ing economic growth via commodity imports and investment in China. Thus, the study confirms the work of Lo et al. Similarly, Douni Kum (2009) employ the Johansen co-integration approach to investigate the relationship between foreign direct investment and economic growth in Nigeria using annual time series data covering the period 1970 to 2007. The study establishes a positive and significant link between foreign direct investment and growth. The Granger causality test also confirms a bidirectional causality running from foreign direct investment to growth. Ogiagah et al. (2010) as well as Douni Kum (2009) also confirm a causal relationship between foreign direct investment and economic growth in Nigeria using annual time series data from 1970 to 2007 of the Sub-Saharan Africa Region. The study reveals a positive and significant long-run relationship between FDI and GDP growth and a unidirectional causality running from GDP to FDI.

Obiamaka and Onwumere (2011) ascertain in depth extent to which growth in foreign direct investment (FDIs) influences economic growth in Nigeria over the period 1980 to 2007 using annual time series data. The study utilized Johansen co-integration technique and discovered a positive long-run relationship between FDI and GDP growth. Saibu et al. (2011) examine the effects of financial development and foreign direct investment on economic growth in Nigeria. Using time series data from 1970 to 2009, the study tests the relationship between variables and adopts the Augmented Granger-Sims-Distributed Lag (ARDL) technique to estimate the model. The results indicate that foreign direct investment had negative effect on economic growth in Nigeria. The result further shows that foreign direct investment is only significant when combined with stock market indicators. The findings of Saibu et al. contradict that of Obiamaka and Onwumere. This could be attributed to the difference in methodology. The Johansen Cointegration test and the Augmented Granger-Sims-Distributed Lag (ARDL) technique yield variation in the results. However, both

studies fail to check for causality between FDI and growth in Nigeria. Similarly, Chukwaka et al. (2012) investigate the relationship between foreign direct investment and GDP growth in Nigeria using annual time series data spanning the period 1960 to 2010. They used Johansen test and the Granger causality approach and find a positive and statistically significant relationship between foreign direct investment and growth and a bidirectional causality from the variables.

Adjay (2009) examined the relationship between FDI and GDP growth in Ghana using annual time series data covering 1970 to 2007. The Johansen and Juselius (1990) multivariate maximum likelihood procedure was employed. The study establishes a positive and significant relationship between FDI and growth. The Granger causality tests confirm a bidirectional causality running from foreign direct investment to growth. Frimpong et al., (2011) disagreed with Adjay when they used the Toda and Yamamoto (1995) to explore the causal link between FDI and growth in Ghana using annual time series data from 1970 to 2002. The results reveal that there is no directional causality between FDI and economic growth for the total sample period and the post-SADC period. However, they did not find a unidirectional causality from FDI to growth during the post-SADC period. The conflicting results could be due to the difference in estimation techniques used. While as Adjay engaged the Johansen and Juselius (1990) multivariate maximum likelihood procedure, Frimpong et al., employed the Johansen and Juselius (1990) multivariate maximum likelihood procedure. The results reveal that there is no directional causality between FDI and growth. In addition, Sackey et al., (2012) employed various econometric tools such as Augmented Dickey Fuller tests, Vector Autoregression and Johansen co-integration tests to study the effect of foreign direct investment on economic growth of Ghana using time series data from 2001 to 2010. They establish a positive and significant long run relationship between FDI and growth and a unidirectional causality running only from FDI to

GD growth in Ghana. Furthermore, Antwe et al. (2013) used annual time series data from Ghana for the period 1980 to 2010. They employed simple ordinary least square regressions and confirm a positive and statistically significant relationship between FDI and growth. However, the study failed to check for directional causality between the two variables. The literature results mixed results on the links between inflation, FDI and growth. Most of the empirical studies are based on cross-sectional and panel data. The cross-country and panel data studies normally average the data over the same periods and across countries from different regions. As a result, they may not reveal a true nature of the relationship between Inflation FDI and growth as such studies are not country specific. Secondly, most of the studies also use a bivariate VAR system to study the links between inflation, FDI and growth. They therefore fall short of a systematic analysis of the impact of host country characteristics as they do not explicitly include control variables into the empirical framework. Consequently, such studies may suffer omission and miss specifications bias and as such their findings may be misleading.

2.6 Foreign Direct Investment (FDI) and Infrastructure Development

The globalization of the world economy has contributed to a remarkable growth of foreign direct investment (FDI) inflow into developing countries in the 1990s. FDI inflow is now acknowledged as a key factor of economic development specifically for developing countries; since it provides the major financial sources to the transfer of technology, organizational and managerial practices and skills, as well as access to international markets (see, e.g., Shatz and Venable, 2000; Alfaro et al., 2004). In particular, multinational enterprises (MNEs) have played an essential role in shaping the patterns of economic development through their FDI decisions (see, e.g., McCann and Mudambi, 2004). Since the 1997 global economic crisis in international financial markets, many developing

ing countries have been strongly advised to rely primarily on FDI inflow for the promotion of economic development on a sustainable basis.

Among various factors associated with the inflow of FDI, infrastructure development is widely considered as a crucial factor influencing the desirability of investment location. The examination of the role of infrastructure development is important particularly for developing countries, such as Ghana, since developing infrastructure is one of the main processes to attract domestic and foreign investors. Moreover, discussion at the regional or provincial level is more important for Indonesia due to an on-going process of decentralization (see, e.g., Silver *et al.*, 2001; Fan, 2003). Given this argument, this study aims at verifying the relationship between FDI and infrastructure development in Ghana. In addition to the role of infrastructure development, this study also attempts to reveal some evidence to explain intra-country determinants of FDI inflows within Ghana. Indeed, an understanding of the determinants of location of FDI inflow could help policy-makers design effective policies to attract FDI inflow into sectors where investment is most needed.

A lot of empirical studies have put more attention on the role of infrastructure development on FDI by using various infrastructure variables covering the quality and the availability of transportation and telecommunications networks. Most of them show the clarity evidence supporting that highly developed infrastructure would play a crucial role in attracting FDI inflows at international or intra-country level. Concerning the Ghanaian economy, few studies have examined the effect of FDI inflows on infrastructure development. For instance, Frempong and Oting-Abayi, (2007) studied the causal link between FDI and GDP growth for Ghana for the pre- and post-SAP periods. In other developing countries, Lisy and Sjoholm (2011) study the relationship between growth and FDI in comparison with other East Asian countries. Moreover, Takii (2005) discusses the role of FDI by

xam ining roductivity s illovs from for i gn multinational lants, and Takii (2011) also xam in s th eff ct of FDI on c onomic growth in r lat ion to th origin of inv s tors in Indon s ian manufacturing ov r th r iod of 1990–2003. D s it th growing im ortanc of FDI inflows in d v 1 o ing c onomi s , m irical v id nc is limit d on th d t rm inants of location choic of FDI inflows at th i r r g ional l v l.

2.7 Conc tual Fram w ork

This s ct ion discuss s th conc tual fram w ork that forms th basis for th m irical s timation. Th fram w ork shows FDI inflows is a function of r lat iv country charact r istics. Th World Inv s tm nt R ort, UNCTAD (1998) has analys d t h d t rm inants of FDI and host country d t rm inants hav b n cla ssifi d into thr grou s. Th s ar olitical factors, busin ss facilitation and c onomic factors. For instanc , horizontal multinationals will b dominant if countri s ar similar in siz and r lat iv nd owm nt s and trans ort costs ar high. If trans ort costs ar low, a firm might rath r x ort than r oduc in both countri s . If countri s ar of diff r nt siz s , national firms might dominat sinc it would b r lat iv ly c ostly to hav an additional r oduction facility in th small country. Conv r s ly, v rtical multinationals should b th dominant ty wh n c ountri s ar diff r nt in siz and/or r lat iv nd owm nt s, with trans ort costs, l gal and olitical conditions (s figur 2.1 b low).

This work how v r follows D m irhan and Masca (2008) fram w ork with slight modification to x lor th ant c d nt s of inward FDI. Lit ratur on FDI and growth also shows a bi-causal r lat ionshi . As th main focus of this study, infrastructur is us d as d nd nt variabl whilst k ing FDI and its driv r s as ind nd nt variabl s .

Independent variables (IV)

CHARTER

RESEARCH METHODOLOGY

3.1 Introduction

This chapter examines the methods used to arrive at the findings of the study. It covers such areas as the specification of the models used for the study, estimation process and description of the data sources and variables selection.

3.2 Research designs

Research designs refer to the overall strategy chosen to investigate the different components of the study in a coherent and logical manner (Vaus, 2001). The main types of research designs identified by Saunders et al. (2007) include experimental, descriptive and explanatory studies.

Explanatory research, as the name suggests, intend to explain the research questions and does not intend to offer final and conclusive solutions to existing problems. It is conducted in order to determine the nature of the problem, explanatory research is not intended to provide conclusive evidence, but helps to have a better understanding of the problem (Brown, 2006). Saunders et al. (2007, p.134) warn that when conducting explanatory research, the researcher ought to be willing to change his/her direction as a result of realization of new data and new insights. Explanatory research designs do not aim to provide the final and conclusive answers to the research questions, but merely explains the research problem with varying levels of depth. "Explanatory research tends to tackle new problems on which little or no previous research has been done" (Brown, 2006, p.43). Moreover, it has to be noted that "explanatory research is the initial research, which forms the basis of more conclusive research. It can very help in determining the research design, sampling method, methodology and data collection method" (Singh, 2007, p.64).

Explanatory research sometimes refers to as analytical studies seeks to identify any causal links between the factors or variables that relate to the research problem (Saunders et al., 2007). Such research is also very structured in nature.

Descriptive research on the other hand can either be quantitative or qualitative. It can involve collections of quantitative information that can be tabulated along a continuum in numerical form, such as scores on a test or the number of times a person chooses to use a certain feature of a

multimedia program, or it can describe categories of information such as gender or attributes of interaction when using technology in a group situation (Hak et al., 1994). Descriptive research involves gathering data that describes variants and then organizes, tabulates, depicts, and describes the data collection (Glass & Hopkins, 1984). It often uses visual aids such as graphs and charts to aid the reader in understanding the data distribution. Because the human mind cannot extract the full import of a large mass of raw data, descriptive statistics are very important in reducing the data to manageable form. When in-depth, narrative descriptions of small numbers of cases are involved, the researcher uses descriptive as a tool to organize data into attributes that merge during analysis. Description merges following categorization, and serves to organize the findings in order to fit them with explanations, and then test or validate those explanations (Krathwohl, 1993).

This study combines both descriptive and explanatory design as they allow for both quantitative and qualitative methods. The use of descriptive design yields rich data that leads to a rigorous analysis. This method also helps to address questions like “what is the effect of FDI on Growth” whilst explanatory research aids in explaining the causal relationships between FDI, Infrastructure and Growth.

3.3 Data Sources

The study uses annual time series data covering the period 1990-2015. The period for the study was chosen based on the availability of data. The data sets were obtained from the World Bank - African Development Indicators Database, the Ministry of Finance and Economic Planning - Fiscal Data. Data used in the overview section and other sections were supplemented with data from ISSR and CA publications. All the variables are in constant prices.

3.4 s timation roc dur

This section re s nt s th s timation roc dur s m loy d in th x loration of th im act of FDI on growth and infrastructur . T im s r i s data of macro c onomic variabl s ar us d; t h s ct ion x lains th various tim s r i s t chniqu s to b us d f or th analysis. Th s timation roc dur s ar und rtak n w ith th aid of Stata 12 and vi w s 8 softwar ackag s .

A two-stag l a st squar s (2SLS) s timation m thod was ado t d w h r for i gn dir ct inv s tm nt wa s nd og n iz d. T h str ngth of this a roach li s in its ability to ov rc om th simultan i ty issus that may aris . Oth r studi s that hav also att m t d t o l iminat th robl m of simultan i ty by ado ting th 2SLS ar Mansouri (2005), Omoniyi & Omobitan (2011) and Av h t al., (2013). T hus, in und rtak ing this study, th 2SLS was r f rr d.

3.4.1 Unit Root T s t

Macro c onomic variabl s usually hav a tim d nd nt m om nt (non-stationary) osing robl m s in th s timation r s ults as th standard assum tions for asym totic analysis would not b valid. As a r s ult, s timating with ordinary l a st Squar s in th r s nc of non-stationary variabl s will l ad t o s urious r s ults. It is critical to t s t wh t h r a g iv n s t of macro c onomic variabl s is stationary or not in tim s r i s analysis such as this. c onom tr icians sugg s t th us of th standard tim - s r i s unit root t s ts nam ly Augm nt d D icky Full r t s t, hilli s- rr on and Dick y -Full r t s t with G n ral iz d L a st Squar s D tr nd ing (DF-GLS) to ch ck th stationarity of variabl s . Th study us s th DF-GLS t s t sinc it is acknowl dg d a s a mor robust. Th DF-GLS is com ut d a s follows:

$$\Delta X'_t = \beta + \rho t + \delta X'_{t-1} + \sum_{\nu=1}^p \gamma_\nu \Delta X'_{t-\nu} + U_t \quad (3.7)$$

where X'_t is the dependent series and t is the time trend. β, δ and Δ are the constant or drift term terms, an arbitrary term and the first-difference operator respectively. γ_{ν} represents the coefficient of the lagged difference terms and U_t is a white noise error term. The DF-GLS regression above tests for the unit root of X_t the logarithm of all the variables at time t . The null and the alternative hypothesis for the presence of unit root in the variable X_t for the DFGLS tests are:

$$H_0 : \delta = 0 \text{ (stationary)}$$

$$H_1 : \delta < 0 \text{ (non-stationary)}$$

The rejection of the null hypothesis leads to the conclusion that the variable is not stationary. Thus autocorrelation persists which will affect the accuracy of the estimates and therefore wrong inference can be drawn. The significance of archaic coefficients requires the use of lags of the variable to achieve stationarity. To determine the optimal lag length (k) of the model the Akaike Information Criterion (AIC) and Schwarz-Bayesian Criterion (SBC) is widely used. The lag length that results in the lowest AIC or SBC is used as the optimal lag length.

3.4.2. Parameter Stability Tests

There is also the need to test the stability of the parameters to be estimated in the models. This is usually done with the use of the cumulative sum of recursive residuals (CUSUM) tests. It is often a reliable when necessary to check for systematic changes in the regression coefficients. Where the tests cross each other, the null hypothesis is that the regression equation is correctly specified is rejected at 5% level of significance level. Macroeconomic variables have been observed to be influenced by structural changes and different policy regimes. Detecting such an influence in the model will call for the need to categorize for this effect in the model specification and the appropriate analytical tool to use.

3.5 Mod 1 Specification

Due to the nature of the research questions and objectives; three (3) major models are built for this study to thoroughly investigate the subject matter and draw meaningful conclusions. Under each model, there are several attempts to construct the theoretical model upon which a particular econometric function is built to examine the research problem.

3.5.1 Mod 1 1 - Antecedents to FDI

This model explores the determinants of FDI inflows in a developing economy with particular reference to Ghana. Literature indicates that there are a large number of variables that explain FDI inflows. In most of the empirical studies reviewed, it is shown that most of the FDI models specifications in empirical studies are based on the "s (1998) classification of the determinants of FDI inflows. Regarding this to say, there is a lack of consensus in the empirical literature concerning the critical determinants of FDI inflows. This work however follows

Dimirhan and Masca (2008) model with slight modification to explore the antecedents of inward FDI. The choice of this model is therefore not based on any distinct theoretical advantages since all models it has been observed from the "s (1998) classification of the determinants of FDI inflows; rather, the choice is necessitated on the basis that it reflects the Ghanaian conditions better. Mathematically, model 1 is specified as:

$$Y_t = F(X_t, Z_t) + V \quad \dots \quad (3.1)$$

Where Y represents the annual inflow of FDI, X is the vector of economic factors; Z comprises the set of legal and political factors. Variables are iid over time whilst $t = 1, 2, \dots, n$ represents the time periods.

The economic variables included in the model are growth rate, real capital (gd), and population size (po) which are proxies for market size; inflation (inf), measured as yearly percentage change in consumer prices and GD growth (grw) – as proxy for economic stability; net exports (nx) – proxy for openness; and M2 as a proxy of GD (Mg), – proxy for financial development and exchange rate volatility – measured as the variance of the US/GHS exchange rate around its mean – proxy for risk.

The legal and political factors include tax (tx), and political uncertainty (0 = low risk, 1 = high risk).

From equation (3.1), a log-linear form of FDI can be specified as:

$$\ln Y_t = \beta + \alpha_i \sum \ln X_{i,t} + \delta_i \sum \ln Z_{i,t} + V \quad \dots \quad (3.2)$$

Where α and δ are the elasticities of economic and legal factors and β is the constant term.

The log-linear estimation is useful to correct for heterogeneity and to achieve uniformity in measurements.

3.5.2 Model 2 – Growth Model

The estimation of model 2 is an attempt to assess the impact of FDI on growth. However according to literature, FDI and growth have a bi-causal relationship. As a result this study endogenizes the FDI in the growth model by incorporating model 1. This technique also has the advantage of correcting any persistent autocorrelation that may likely occur due to omission of relevant variables. A similar approach has also been outlined in the works of Asafu-Adjay, (2005); Omoniyi & Omobitan, (2011) and Avah, Krah and Dadzi, (2013).

A Solow production model is specified following the recommendations of Mendez-Bravo et al. (2012) who concluded that the Solow's production function is ideal for explaining and predicting economic growth in Ghana.

$$Y_t = F(K, L, A) \quad \text{--- (3.3)}$$

From the model above, Solow identified total factor productivity (A) as the key determinant of growth in the long term. K represents capital and L for Labour. The general form for Solow's production function used by empirical studies to specify the input-output relationships in developing economies is written as (Omoniyi & Omobitan, 2011):

$$grw_t = \beta_0 + \beta_1 \frac{I}{grw_{t-1}} + \beta_2 L^g + \beta_3 W^g \quad \text{--- (3.4)}$$

Where grw_t = growth rate of GDP; grw_{t-1} = lagged growth rate of GDP; L^g = growth rate of Labour; I = domestic capital formation; W^g = growth rate of other variables influencing total factor productivity; and β_0 = constant assumed to be growth of productivity; whereas $\beta_1, \beta_2, \beta_3$ are parameters to be estimated in the model.

Among the numerous variables observed to influence total factor productivity in developing countries include growth of exports, inflation, FDI and agricultural growth rates (Asafu-Adjay, 2005; Omoniyi & Omobitan, 2011). On the basis of equation 3.4, the following production function is specified for this study:

$$grw_t = \beta_0 + \beta_1 I^g + \beta_2 L^g + \beta_3 FDI + v \quad \text{--- (3.5)}$$

Where growth is a function of labour (L), domestic capital (I), and foreign direct investment (FDI) respectively is formulated and v = error term.

3.5.3 Mod 1 3 – Infrastructure Mod 1

Mod 1 3 considers the impact of FDI inflows on infrastructure. Again, based on previous knowledge in the literature, FDI is endogenous in the following model. The infrastructure model is formulated as:

$$infra_t = \beta_0 + \beta_1 lnI + \beta_2 lnL + \beta_3 lnFDI + \beta_4 lnH + v \quad (3.6)$$

Where $infra$ is the log of level of infrastructure, I denotes domestic capital formation; L = labour; H = human capital formed by enrollment in tertiary education and very recent disturbance term.

CHAPTER FOUR

DATA ANALYSIS AND RESULTS

4.1 Introduction

This chapter focuses on analyzing the data and presentation of results. It includes discussions of the findings against previous literature concerning the impact of foreign direct investment on growth and infrastructure in Ghana. The analysis is conducted with a descriptive summary of the annualized data from 1991 – 2015 and trend analysis of the key variables – FDI, growth and infrastructure. The next section was then to form the stationarity tests using mainly the DGLS process. Testing the stationarity process of the observed variables, they were then transformed accordingly and the third estimation performed; in the third section, using all the appropriate models. The results are presented based on the study objectives for purposes of coherence and readability.

4.2 Results Objectives 1

To benefit from the discussion of the effect of FDI on growth and Infrastructure, the study objectives is designed to find out what the trends and nature of the observed variables have been over the last two decades. This was necessary to offer firsthand information and ictorial description of the flow and relationship of the macroeconomic variables. The focus is to put the discussion into its proper context so that any further analysis will seek to offer a detailed explanation of the behavior of the variables identified.

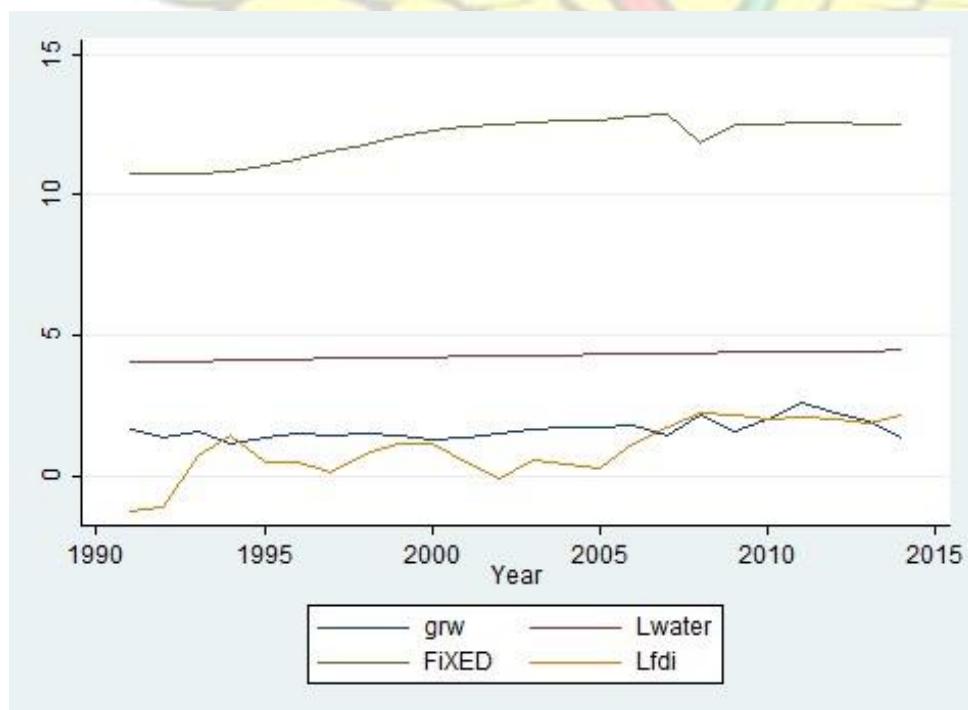

4.2.1 Trends of FDI, Growth and Infrastructure from 1990-2015

There is a general increase in the inflows of foreign investment over the same period; however, it is shown that between 1994 to 2002 share falls in the FDI inflows were present. It is however assumed its steady rise onwards to 2014. The average growth rate for the 25-year period was 0.99% faster than the annual change in GDP growth of 1.66% for the data set. However, figure 4.1 shows evidence of convergence. Standard deviation of both the GDP growth and FDI inflows indicates that for the last 25 years FDI has been more volatile than the GDP growth. This reflects the fact that much variability is observed in the annual FDI inflows unlike in GDP growth. In particular the random sites (standard deviation) shows less spread out with flat right for the GDP growth rate than the FDI. This shows that Ghana has had long periods of slow growth in recent years; meanwhile, FDI distribution reveals many years of high FDI inflows. Until 2007/2011, annual change in GDP growth rates has been marginal. The advent of the oil production in 2010 saw a peak in GDP growth but soon after a downward spiral. What this study is yet to answer is whether the long periods of significant growth in FDI inflows has had any significant impact on the economy. This trend conforms to the work of Tsikata et al. (2000) which report that 1993-1996 was a

iod of significant, but oscillatory inflows, which peaked in 1994 at \$233 million, but fell by more than 50% the following year to \$107 million.

It is suggested from figure 4.1 how very little information is available; but there is little information to suggest causality or no causality at this point.

Regarding infrastructure, represented by the total number of telephone subscribers (fixed line) and access to water; a significant annual growth rate is also evident. Descriptive summary shows an annual growth rate of 12% for fixed line subscribers whereas for access to water, results illustrate a 4.2% annual mean. Standard deviation is also large, which suggests high variations in the number of yearly subscription in telephone communication. One thing is clear; that the annual growth in infrastructure (fixed lines and access to water); in particular fixed line subscribers, is more than the growth in FDI inflows and GDP growth combined. **Figure 4.1: Trends in FDI, Real GDP growth and Infrastructure**

The Kurtosis, Skewness and Jarque-Bera statistics prove that all the variables are normally distributed.

Table 4.1: Descriptive Summary of Variables

4.3 Econometric Results

The question that arises on any critical mind, given that trends in the observed variables is; does the FDI inflow have any significant influence on the GDP growth and infrastructure? To answer this question requires a time analysis of the quantities specified in the previous chart.

4.3.1 Unit Root Tests

Due to the challenges associated with time series data, there was the need to take steps to ensure that the data was reliable for any analysis. A unit root test is performed to examine if the series (both endogenous and exogenous) have any temporal dependency as characteristic of time series data. The temporal dependency of any time series is referred to as non-stationarity. Grang

r and Nwb old (1974) demonstrate that if two independent non-stationary series are regressd on each other the chance of attaining a spurious relationship is very high.

Table 4.2 depicts the results of the Dickey Full Giraldo-Laatsch-Squares unit root tests. The relevance of the unit root testing is to ensure that all the variables are $I(0)$ before any regression analysis is performed. The results show that the null of non-stationarity is to be rejected at 5% critical values at levels for GDP growth, labour (foreign trade), investment, exports, inflation and infrastructure. However, FDI, exchange rate, population size and infrastructure are proxied by number of telephone subscribers which are first difference stationary.

Table 4.2: Dickey Full Giraldo-Laatsch-Squares Unit Root Tests

+Stationary with trend and intercept

4.3.2 Results Objectives 2: Analysis of FDI Inflows

The results of the DGLS unit root tests as displayed on Table 4.2 above indicate that most of the variables are stationary at level except for FDI, population size, and exchange rates which are first order stationary. Economists conclude that generally when variables of different orders of integration are combined in a regression, the combination will have an order of integration equal to the largest. As a result since all the variables are $I(1)$ stationary, it was consistent to conclude that these series are integrated of order one. It is suggested by Engle and Granger (1987) that macroeconomic non-stationary time series variables may be moving together and only over time cyclically along the business cycle. Thus a linear combination of these variables in a model may lead to a curious regression that suggests serial correlations even when there are none. However if a linear combination of these variables is stationary $I(0)$, then the variables are said to be co-integrated; hence they have a long-run relationship. That is co-integration is said to exist between two or more non-stationary time series if they possess the same order of integration and a linear combination

(weight distribution) of the series is stationary. Since some of the observed variables are non-stationary, it is redundant to check if a co-integration relationship exists before the actual modeling is conducted. The implication is that non-stationary variables can lead to spurious regressions unless at least one cointegration vector is robust enough that some form of testing for cointegration is almost mandatory.

Before FDI model is estimated, the Johansen co-integration test is performed. Table 4.3 and 4.4 report the results of the Likelihood Ratio tests based on the Trace and the Maximum eigenvalue of the stochastic matrix respectively. Both tests confirm the existence of three cointegrating vectors between the variables, i.e., the existence of long-run relationships between them.

* denotes rejection of the hypothesis at the 0.05 level.

**MacKinnon-Haug-Michelis (1999) -values

Since the variables are cointegrated, they can be represented simultaneously in terms of a long run Fully Modified Least Squares framework (FMOLS) of hills and Hansen (1990). The FMOLS is also shown to give better estimates in small samples.

$$FDI = \beta_0 + \beta_1 FDI_{t-1} + \beta_2 POP + \beta_3 INF + \beta_4 OPEN + \beta_5 RE + \beta_6 RISK + \beta_7 GRW + \beta_8 IR + \varepsilon$$

----- (4.1)

The FMOLS is a likelihood to estimate determinants of FDI inflows in Ghana using equation 3.2 as specification in the various chart. The econometric model of equation 3.1 is specified above in equation 4.1; where FDI is the log of the FDI inflows, POP is the ratio of the log of the ratio of population size to GD . This was introduced in the modelling to depict the production capacity of the economy; against the growing market size. High ratios do not lower capacity, as the size of the population is growing faster than the economy can allow. For a sake of interpretation, POP was inverted by multiplying by -1 and then adjusted by adding 1. Any ratio above unity; therefore implying that output was growing above the size of the market. INF is the log of inflation rates. $OPEN$ represents the log of total trade volume (exports + imports) as a percentage of GD . This was to measure the level of openness of the economy. RE is the standard deviation of the log difference of the real exchange rates around its annual mean. This is to proxy the volatility in the US dollar/Ghana Cedi exchange rate. Risk is a dummy of 1 for the year; GRW represents the log of the real GD growth rates, IRD notes the level of the nominal interest rates proxied by the 91day treasury bill whilst ε_t is the disturbance term.

To initial the analysis, a descriptive and correlation analysis were performed. Table 4.5a and Table 4.5b present the summary and correlation statistics of the independent and dependent variables averaged over the 1990-2015 period. Results show a considerable annual variation in the production capacity (O), inflation rate, interest rates and openness. Table 4.5b reporting the results of the correlation analysis reveal that there is no problem of multicollinearity among the variables. Though not suggesting causality, the correlation table depicts a positive correlation between FD

I inflows, and production capacity (O) and growth. A negative association was however suggested in its links with exchange rate fluctuations, inflation,

output, interest rates and the risk factor.

Th co ff ici nt of -4.439332 of R indicat s that any 10% incr a s in th xc hang rat around its m an w ill r s ults in a 44.4% d cl in in FDI inflows. Furth rm or , th r s ults su ort d t h tariff-jum ing hy oth s is which stat s that for i gn firms which s k to s r v local mark t s may d c id to s t u subsidiaries in th host country if it is

difficult to import them products to the country. The study results show that a 10% tightening of Ghana's traditional "windows" results in a 23% reduction in FDI inflows.

Again, results indicate that the more risky the political landscape in Ghana is, the less is the amount of inflows received. In particular as the country gravitates from non-lection during year to an election during year, there is a significant reduction in FDI inflows by 0.3%. However, the study results show that previous level of FDI inflows have a positive effect on current level of FDI inflows significant at 1%.

D₁ and D₂ are independent variables: FDI

Source : Author (2016)

The results also show that GD growth has a long run negative relationship with FDI inflows. Specifically a 10% increase in GD growth will induce a more than 23% reduction in FDI inflows. This suggests the scenario "retirement" effect associated with increased FDI; where multinational firms push out domestic firms without FDI out of the market. The model's explanatory power using the adjusted R² is validated at around 85% level. The implication is that 85% of the variations in FDI inflows can be explained by the economic and legal/political factors included in the regression model. Based on this study, it is decided to examine how FDI inflows also influence real GD growth.

4.3.3 Research Objectives 3: The effect of FDI Inflows on Growth

Based on the FDI-Growth model specified in equation 3.5, the effect of FDI inflows on real GD growth was also investigated. Again before any empirical analysis was conducted, there was the need to check for possible cointegration among the variables. The Johansen co-integration test was consistently performed. Table 4.7 and 4.8 report the results of the Likelihood Ratio tests based on the Trac and the Maximum eigenvalue of the stochastic matrix respectively. Both tests confirm the existence of three cointegrating vectors between the variables.

Two (2) estimation approaches were used to calculate the effects of FDI on growth. The first one involved a 2 SLS approach, where the predicted values of equation 4.1 were used to represent FDI in the current model (see Tabl 4.10a). This was attempted to correct for possible simultaneity and endogeneity in the growth model. Nonetheless, the actual values of the log of FDI inflows were used in the second estimation and the results compared (see Tabl 4.10b).

Results show that among the control variables used in the FDI-Growth model, investment, GDP capita, and lagged GDP growth rate have a strong impact on real GDP growth rates. A 10% increase in investment is shown to have 5.8% output growth in real GDP growth in the first model (Table 4.10a); whilst on Table 4.10b it is observed to have a 4.7% increase in real GDP growth. Second, it is shown that market size also impacts on growth. A 10% increase in GDP capita is shown to have a long run increase in real GDP growth rate by 22% in Table 4.10a and 23% in Table 4.10b. Results also confirm the indication of convergence in the real GDP growth rate. The coefficient of lagged GDP growth rate is negative and significant at 5% in both models. In regression Table 4.10a the coefficient of lagged GDP growth rate corresponds to a 0.38% output points while on Table 4.10b, it corresponds to a 0.39% output points to its long run equilibrium path. FDI was shown not to draw any significant impact on growth in both models. The strength of both models is validated by the adjusted R-squares of 70.5% in the first model and 71.9% in the second model. This result is no different from what was found in literature, the results by Ramírez (2000) indicate that for the period 1960-1995, FDI Granger-causes growth in Mexico. The study also establishes a positive relationship between FDI and growth in both the short and the long run relationships. In addition, Athukorala (2003) examine the relationship between FDI and growth using time series data from

the Sri-Lankan economy. The economic results show a positive and significant relationship between FDI and economic growth. Furthermore, Looss et al. (2010) examine the linkages and directional causality between FDI and growth of ten Sub-Saharan African countries using annual time series data from 1970 to 2007. They employ the Saran et al. (2001) approach to co-integration and the Toda and Yamamoto (1995) causality test and realize a positive and significant long-run relationship between FDI and GDP growth in Angola, Liberia, Kenya and South Africa. However, they found a unidirectional causality running from FDI to GDP growth. Both Looss et al. and Ogiagah et al. have the same opinion on the relationship between FDI and growth.

4.3.4 Research Objectives 4: The effect of FDI Inflows on Infrastructure

Among various factors as a determinant of FDI inflows, infrastructure development is widely considered as a crucial factor influencing the desirability of investment location. The examination of the role of infrastructure development is important particularly for developing countries, such as Ghana, since developing infrastructure is one of the main reasons to attract domestic and foreign investments.

Following the previous approaches, thus, of the FMOLS framework was made to assess the effect of FDI inflows on infrastructure. In principle, it was necessary to check if a linear combination of the sum of the non-stationary series would be stationary. The Likelihood Ratio tests based on the Trace and the Maximum eigenvalue of the stochastic matrix were checked and results are presented on Tables 4.11a and 4.11b respectively. Both tests confirm that existence of two co-integrating vectors between the variables.

Having justified the usefulness of the Fully Modified Least Squares (FMOLS) regressions, the study commences to model the FDI-Infrastructure relationship. The economic model of equation 3.6 in the chapter 3 was therefore specified as:

$$Infra = \beta_0 + \beta_1 Infra_{t-1} + \beta_2 Lab + \beta_3 FDI + \beta_4 INV + \beta_5 GRW_{t-1} + \beta_6 Year + \varepsilon \quad (4.3)$$

Where $Infra$ is the log of infrastructure (proxied by the number of fixed telephone subscribers and access to quality water). FDI represents the log of FDI inflows. The model controls for the effect of labour force, Lab ; investment, INV ; GDP growth rates, GRW ; and time, $Year$. All the variables are specified in logs.

Similarly, two (2) estimations approach were used to capture the effects of FDI on infrastructure. The first one involved a 2SLS approach, where the predicted values of equation 4.1 were used to represent FDI in the current model (see Table 4.12a). Again, this was in an attempt to correct for possible simultaneity and endogeneity in the model; i.e., capturing the effects of other factors which may also influence the level of infrastructure but not included in the modeling. Nonetheless, the actual values of the log of FDI inflows were used in the second estimation and the results compared (see Table 4.12b). It is important to clarify at this point that the effect of FDI will be assessed individually on infrastructure in the telecommunications (fixed line subscribers) and then access to quality and portable water and telephone.

Results show that FDI inflows have a negative impact on infrastructure. In the first model, under both accessibility to water and fixed line subscriptions, the results reveal a significant negative

ff ct. According to ODI (1997), poor infrastructure can be seen, however, as both an obstacle and an opportunity for foreign investment. For the majority of low-income countries, it is often cited as one of the major constraints. But for investors, it is also important to the potential for attracting significant FDI if host government structures are more substantial for participation in the infrastructure sector. Jordaan (2004) claims that good quality and well-developed infrastructure increases the productivity potential of investments in a country and therefore stimulates FDI flows towards the country.

In the second model, under the direct approach, results show that telecommunications infrastructure is strong negative impact ($B = -0.238; < 5\%$); but its effect on water is rather weak though also negative. This result is rather interesting, given the fact that most FDI in Ghana has been involved in recent times in agriculture, construction, extractive industry, and in particular mining; where these activities are suggested to have a direct impact third party effects on the surrounding communities. Again, it is shown in both models that there are strong increases in infrastructure annually.

A: Predicted values of FDI from equation 4.1

Dependent Variable: Infrastructure

Source : Author (2016)

Results show a range of between 0.10% - 0.12% for telephone communication annually; based on Table 4.12b and Table 4.12a displays. For water, it is shown that access to water increases by the range of 0.004% to 0.056% yearly. The results are all significant at less than 5% critical levels. Furthermore, the results show that investment in labour does not draw any effect on telephone communication infrastructure; rather on water in both estimations. For Table 4.12a, it is shown that

10% increase in labour draws a 0.05% increase in access to water; whereas for Table 4.12b, it is shown to induce a 0.7%, significant at less than 1%. The study also found evidence to suggest that previous growth in infrastructure has a strong positive impact on current growth in infrastructure. For telephone communication, it is shown that lagged infrastructure induces 0.3% and 0.4% increases in current infrastructure in Table 4.12a and Table 4.12b respectively.

B: predict values of FDI from equation 4.1

Dependent Variable: Infrastructure

Source : Author (2016)

For what accessibility, results show that it induces 0.68% increase in current infrastructure (in Table 4.12a) whereas in the second model it is shown to induce a 0.75% increase on current infrastructure. The results on the long run impact of GDP growth were interesting. In both models, it is shown that as the economy grows; the number of fixed line subscribers decreases at 0.9% in the first model and 0.8% in the second model. Similar results was found for water; however whilst the first model shows a strong negative impact ($B = -0.003; < 10\%$), the second model reveals that the relationship was rather weak. The robustness tests for the models were all good; showing a good fit between the models and the data. The adjusted R-Squared also validated all the models ranging from 83% to 99%.

4.4 Discussion of results

This work focuses on investigating the causal relationships between economic growth, FDI and infrastructure. First the results of the study shows that regional investment is influenced directly by such factors including fluctuations in the level of exchange rates, trade openness and the political landscape. The results on trade openness provide evidence for the tariff-jumping or export substitution hypothesis which states that as trade openness contracts, foreign investors are likely to establish domestic subsidiary companies in order to overcome the import restrictions.

Again, the work provided support for the results of Schnider and Fry (1985); as well as Lor and Guisinger (1995) who found that for foreign investors and for that matter FDI inflows are likely to

hold back or reduce when the rate is a reason to suspect that the political economy is risky. Meanwhile, the study results show that exchange rate volatility is a major disincentive to the choice of the Ghana as an FDI destination as it adds to the list of financial risks that must be born by investors. Particularly the work supports a similar study conducted by Ogunleye (2009) using Nigeria and South Africa as a case study. The author found that exchange rate volatility has a detrimental effect on FDI inflows, with FDI inflows aggravating exchange rate volatility in both countries. Moreover, studies such as Tokunbo and Lloyd (2009) in Nigeria; Kyebah Colman and Tettey (2008) in Ghana; and Kiyota and Urata (2004) provide empirical evidence to support the conclusion that exchange rate volatility has a harmful effect on FDI inflows. It is therefore required of the Bank of Ghana to find a way to obtain a stable exchange rate in real terms so that production is not handicapped to bring about a positive increase in real FDI along with internal and external balance maintenance. The harmful effect of an unstable exchange rate lies in the fact that it could potentially reduce investors' interest and make it difficult to attract capital.

Interestingly relating to the relationship between GDP growth and FDI, the study results reveal a unidirectional causality between the two variables; unlike the bidirectional relationship suggested in some empirical studies. Specifically it is found that whilst GDP growth has a negative and significant impact on FDI; FDI has a weak but negative effect on growth. Carkovic and Levin (2002) for instance tried to assess the relationship between FDI and economic growth for 72 countries over the period 1960-1995. Their results indicate that for both developed and developing economies FDI inflows did not exert any significant influence on economic growth. Specifically the foreign-owned component of FDI did not exert a reliable positive impact on economic growth,唯有 all owing for the level of education, the level of economic development, the level of financial development and trade openness of the recipient country. Meanwhile, Barrill and

(1999) concluded that FDI may affect the host country's performance positively in cases where the transfer of technology and knowledge through FDI to the host economy. The study results show that there is a significant relationship between FDI in Ghana, where multinational firms push out domestic firms without FDI out of the market. Referring to the determinants of economic growth, it is shown by the results that, investment, GDP capita, and lagged GDP growth rate have a strong impact on real GDP growth rates. More interestingly, we found evidence of convergence in the growth rate over time.

Focusing on the effect of FDI on infrastructure, the study results show that inflows have a negative impact on infrastructure; in particular, a strong negative effect was found for fixed line subscription whilst in terms of access to water, a mixed effect was observed. This result is rather interesting, given the fact that most FDI in Ghana has received in recent times are direct due to the extractive industry, and in particular mining; where their activities are suggested to have a detrimental impact on the surrounding communities. Referring to fixed lines as proxy for infrastructure, FDI is expected to lead to improvement in technological development – through the development of ICT and new communication technologies. Since fixed lines are more analogous and traditional; the strong negative effect is to be expected. Mainly for water resources, whilst a negative effect was found, it is shown that in the direct model, the effect is weak whilst in the instrumental model; a strong negative impact was found. This therefore suggests that on the whole, increases in foreign direct investment have not led to any improvement in water accessibility in the country. Moreover, it is generally given the background that most of the investors are seeking to make huge returns on their investments, they may not be so much concerned about the environment or the community life. Typical examples are the differentious activities of Chinese operators in the small-scale mining sector. It was in view of this that the government of Ghana in July, 2013

task d a j oint olic , m ilitary and immigration t am to flush out ill gal m ining o rat ors which l d t o th arr s t of ov r 270 C hin s and oth r f or i gn nationals. In Ghana, th rinci al n vironm ntal robl m s caus d by small-scal mining activity ar m rcury ollution from gold roc ss ing, wat r ollution and land d gradat ion.

SUMMARY OF FINDINGS, CONCLUSION AND R C OMM NDAT IONS

5.1 Introduction

This chapter presents the summary of findings from the previous, conclusion and recommendations. As may be recalled from the previous chapter, the analysis sought to examine the impact of foreign direct investment on growth and infrastructure in Ghana using a descriptive summary of the annualized data from 1991 – 2015 and trend analysis of the key variables – FDI, growth and infrastructure. After testing the stationary process of the observed variables, they were then transformed accordingly and then the estimations formed using appropriate models.

This chapter deals with a more concise observation based on the study.

5.2 Summary of Findings

Below is a summary of findings made from the previous chapter:

5.2.1 Objectiv 1: The pattern of FDI inflows in Ghana over the last two decades

The study found a general increase in the inflows of foreign investment over the same period; however, it is shown that between 1994 to 2002 sharp falls in the FDI inflows were seen. It however varies considerably upwards from onwards to 2014. The study also found that average growth rate for the 25-year period was 0.99% far less than the annual change in GDP growth of 1.66% for the data set. Standard deviation of both the GDP growth and FDI inflows

indicates that for the last 25 years FDI has been more volatile than GDP growth. This reflects the fact that much variability is observed in the annual FDI inflows unlike in GDP growth.

Regarding infrastructure, represented by the total number of telephone subscribers (fixed lines) and access to water; a significant incremental annual change is also evident. The study found an annual growth rate of 12% for fixed line subscribers whereas for access to water, results illustrate a 4.2% annual mean. The study also found that the annual growth in infrastructure (fixed lines and access to water); in particular fixed line subscribers, is more than the growth in FDI inflows and GDP growth combined.

5.2.2 Objectives 2: Antecedents of FDI Inflows into Ghana

An initial analysis was performed using descriptive and correlation. The study found a considerable annual variation in the production capacity (O), inflation rate, interest rates and ones. Regarding the results of the correlation analysis revealed that there is no problem of multicollinearity among the variables. Though not suggesting causality, the correlation table depicts a positive relationship between FDI inflows, and production capacity (O) and growth. A negative association was however suggested in its links with exchange rate fluctuations, inflation, ones, interest rates and the risk factor.

The long run FMOLS estimation showed that *ones, GDP growth rate, exchange rate fluctuations, political risks and previous level of FDI inflows* have a strong impact on current FDI inflows at 5% significance level. Meanwhile the study found that production capacity, inflation rate and current level of interest rates did not have any impact on current FDI inflows. The study also

found that high fluctuations in the exchange rates have a direct influence on current inflows. The coefficient of -4.439332 of R^2 indicates that any 10% increase in the exchange rate around its mean will result in a 44.4% decline in FDI inflows.

The findings also support the tariff-jumping hypothesis which states that foreign firms which seek to preserve local markets may decide to establish subsidiaries in the host country if it is difficult to import their products to the country. The study results show that a 10% tightening of Ghana's trade "windows" results in a 23% enhancement in FDI inflows. Again, the findings indicate that the more risky the political landscape in Ghana, the less rather the amount of inflows received. In particular as the country gravitates from non-licitation rating year to an licitation rating year, there is a significant reduction in FDI inflows by 0.3%. However, the study results show that revenue level of FDI inflows have a positive effect on current level of FDI inflows significant at 1%.

The study also found that GDP growth has a long run negative relationship with FDI inflows. Specifically a 10% increase in GDP growth will induce a more than 23% reduction in FDI inflows. This suggests the scenario "retirement" effect associated with increased FDI; where multinational firms push out domestic firms without FDI out of the market. The model "sanitary" ruling using the adjusted R^2 is validated around 85 percent. The implication is that 85% of the variations in FDI inflows can be explained by the economic and legal/political factors included in the regression model.

5.2.3 Objectives 3: The effect of FDI Inflows on Growth

As part of the objectives of the study, the effect of FDI inflows on real GDP growth was also investigated. Two (2) estimations approach was used to capture the effects of FDI on growth. The first one involved a 2 SLS approach, where the predicted values of equation 4.1 (several variables) were used to regress FDI in the current model (see Table 4.10a). This was in an attempt to correct for possible simultaneity and endogeneity in the growth model. Nonetheless the actual values of the log of FDI inflows were used in the second estimation and the results compared (see Table 4.10b).

The study found that among the control variables used in the FDI-Growth model, investment, GDP ratio, and lagged GDP growth rate have a strong impact on real GDP growth rates. A 10% recent increase in investment is shown to have 5.8% increments in GDP growth in the first model (Table 4.10a); whilst on Table 4.10b it was observed to have a 4.7% increase in GDP growth.

The study also found that market size impacts on growth. A 10% increase in GDP ratio is shown to have a long run increase in GDP growth rate by 22% in Table 4.10a and 23% in Table 4.10b (referring to previous chapter). Results also confirm the indication of convergence in the GDP growth rate. The coefficient of lagged GDP growth rate is negative and significant at 5% in both models. In regression Table 4.10a (referring to previous chapter) the coefficient of lagged GDP growth rate corresponds to a 0.38 coefficient while on Table 4.10b, it corresponds to a 0.39 coefficient due to its long run equilibrium path.

Interestingly, FDI was shown not to draw any significant impact on growth in both models. The strength of both models is validated by the adjusted R-squareds of 70.5% in the first model and 71.9% in the second model.

5.2.4 Obj et iv s 4: Th ff ct of FDI Inflows on Infrastructur

Following th r v ious a roach s , th us of th FMOLS fram w ork was mad to ass ss th ff ct of FDI inflows on infrastructur .

The study found that FDI inflows hav a n gat iv im act on infrastructur . In th first mod l, und r b oth acc ss ibility to wat r and fix d l in s subscr iptions, th r s ults r v al d a significant n gat iv ff ct. In th s c ond mod l, und r t h dir ct a roach, r s ults show d t hat for t1 c ommunications, th r is strong n gat iv im act ($B = -0.238; < 5\%$); but its ff ct s on wat r is rath r w ak t hough also n gat iv . T his r s ult is rath r int r s ting, giv n t h fact that most FDIs that Ghana has r c i v d in r c nt t im s ar dir ct d t o th xtract iv industry, and in articular mining; wh r th i r activiti s ar sugg s t d t o hav a d tr im ntal t hird arty ff ct s on th surrounding communiti s .

Again, it is shown in both mod l s that th r ar rc nttag incr a s s in infrastructur annually.

The findings show a rang of b tw n 0.10% - 0.12% for t1 c ommunication annually; bas d on Tabl 4.12b and Tabl 4.12a dis lays (s r v ious cha t r). For wat r, it is shown that acc ss to wat r incr a s s by th rang of 0.004% to 0.056% y arly. T h r s ults ar all significant at l ss than 5% critical l v 1 s. Furth rm or th r s ults show that rc nttag incr a s s in labour do s not draw any ff ct on t1 c ommunication infrastructur ; rat h r on wat r in both s timations. For Tabl 4.12a, it is shown that 10% incr a s in labour draws a 0.05% incr a s in acc ss to wat r; wh r a s for Tabl 4.12b, it is shown to induc a 0.7%, significant at l ss than 1%. T he study also found v id nc to sugg s t that r v ious growth in infrastructur has a strong ositiv im act on curr nt gr owth in infrastructur . For t1 c ommunication, it showed that lagg d infrastructur induc s 0.3% and 0.4% incr a s in curr nt infrastructur (s Tabl 4.12a and Tabl 4.12b r s ct iv ly).

For water accessibility, the study found that it induces 0.68% increase in current infrastructure (in Table 4.12a) whereas in the second model it is shown to induce a 0.75% increase on current infrastructure.

The results on the long run impact of GDP growth without testing. In both models, it is shown that as the economy grows; the number of fixed line subscribers decreases at 0.9% in the first model and 0.8% in the second model. Similar result was found for water; however whilst the first model shows a strong negative impact ($B = -0.003$; $< 10\%$), the second model reveals that the relationship was rather weak. The robustness tests for the models were all good; showing a good fit between the models and the data. The adjusted R-Square also validated all the models ranging from 83% to 99%.

5.3 Conclusion

This work focused on investigating the causal relationships between economic growth, FDI and infrastructure. First the results of the study reveal that direct investment is influenced directly by such factors including fluctuations in the level of exchange rates, trade openness and the political landscape. The results on trade openness provided evidence for the tariff-jumping or export substitution hypothesis which states that as trade openness contracts, foreign investors are likely to establish domestic subsidiary companies in order to overcome the import restrictions. Again, the work provided support for the results of Schindler and Frey (1985); as well as Lor and Guisinger (1995) who found that for foreign investors and for that matter FDI inflows are likely to hold back or reduce when there is a reason to suspect that the political economy is risky. Moreover, the study results show that exchange rate volatility is a major disincentive to the choice of Ghana as

an FDI destination as it adds to the list of financial risks that must be born by investors. Particularly the work supports a similar study conducted by Ogunleye (2009) using Nigeria and South Africa as a case study. The author found that exchange rate volatility has a detrimental effect on FDI inflows, with FDI inflows aggravating exchange rate volatility in both countries. Moreover, studies such as Tokunbo and Lloyd (2009) in Nigeria; Kyeremeh-Colman and Tettey (2008) in Ghana; and Kiyota and Urata (2004) provide empirical evidence to support the conclusion that exchange rate volatility has a harmful effect on FDI inflows.

On the relationship between GDP growth and FDI, the study found a unidirectional causality between the two variables. Specifically, it is found that whilst GDP growth has a negative and significant impact on FDI; FDI has a weak but negative effect on growth. Carkovic and Levine (2002) for instance, find that there is a strong negative relationship between FDI and economic growth for 72 countries over the period 1960-1995. Their results indicate that for developing and developed emerging economies, FDI inflows did not exert any significant influence on economic growth. The study results show that there is a strong negative relationship between FDI in Ghana, where multinational firms push out domestic firms without FDI out of the market. Referring to the determinants of economic growth, it is shown by the results that, investment, GDP ratio, and lagged GDP growth rates have a strong impact on real GDP growth rates. More interestingly, we found evidence of convergence in the growth rate over time.

Focusing on the effect of FDI on infrastructure, the study results show that inflows have a negative impact on infrastructure; in particular, a strong negative effect was found for fixed line subscription whilst in terms of access to water, a mixed effect was observed.

5.4 Recommendations

In line with the findings above, the research makes the following recommendations:

5.4.1 Correction of Microeconomic Imbalances

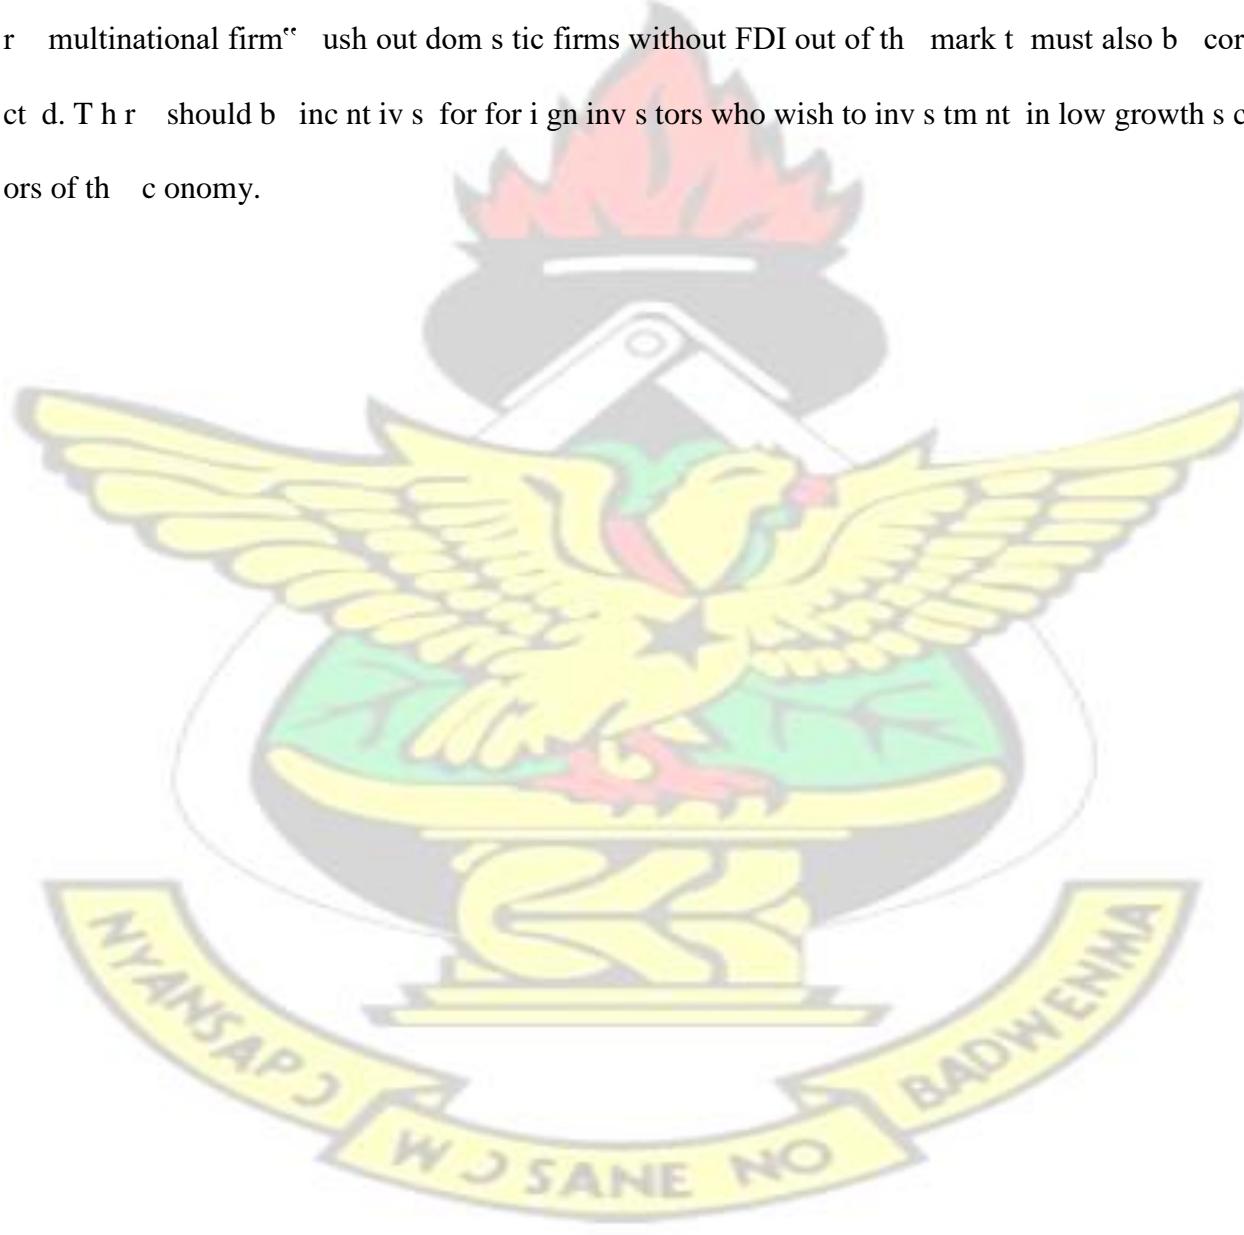

First, there is need for government to work at correcting macroeconomic imbalances. By this, the Bank of Ghana and the Ministry of Finance and Economic Planning must endeavour to obtain a stable exchange rate in real terms so that production is enhanced to bring about a positive increase in real FDI along with internal and external balance maintenance. The harmful effect of an unstable exchange rate lies in the fact that it could potentially reduce investors' interest and make it difficult to attract capital. Investors must be under control. More important is correcting the country's balance of payments deficit by reducing imports or promoting exports.

5.4.2 Redirecting of FDI to Growth Inducing Sectors

To achieve growth in infrastructure, Government should work at ensuring that FDI is attracted to sectors of the economy that directly triggers growth. Even though areas such as water provision may not be attractive to some investors, government could turn to Center for Scientific Research (CSR) activities when trying to recruit willingness for these investors. Sectors such as Agriculture, Commerce and energy infrastructure should also be looked at. As shown in the 2016 budget statement, Agriculture has performed woefully. There is therefore the need to encourage investment into the sector. The energy sector has also been in crisis over the last decade. It is therefore redundant that government takes the bull by the horns to deregulate power generation and distribution stages of the energy supply chain.

5.4.3 Opening Country Up for More Trade

To attain a high level of growth, it is important to open the country's market further. However, a careful analysis should be done to identify sectors that warrant openness. It is also important that foreign direct investments are channeled to nascent industries instead of markets with already high levels of saturation. This scenario of "rent seeking" often associated with inward-looking FDI where multinational firms push out domestic firms without FDI out of the market must also be corrected. There should be incentives for foreign investors who wish to invest in low-growth sectors of the economy.
